LONDON HOSPITAL MEDICAL COLLEGE & DENTAL SCHOOL.

THE WINTER SESSION will Open on Tuesday, October 1st.

The Hospital is the largest in England. There are 839 beds in constant use. Last year: number of in-patients 14,698; new out-patients, 96,928; attendances, 555,762; new dental patients, 5,857; major operations, 7,649.

The MEDICAL COLLEGE and DENTAL SCHOOL are essentially modern, with large laboratories equipped with the latest and the most approved appliances. The STAFF is so large as to permit of individual attention being paid to all Students.

MEDICAL UNIT.—A Clinical Unit in Medicine, under the charge of a whole-time Director, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research.

RESEARCH FUNDS to the value of over £115,000 permit of financial assistance being given to Students and Graduates engaged in Medical Research.

SCHOLARSHIPS and PRIZES to the value of £1,158 are awarded annually, including four Open Entrance Scholarships to the value of £350, and two Entrance Scholarships open to students of the Universities of Oxford and Cambridge to the value of £200.

APPOINTMENTS.—Over 160 Appointments are made annually from Students of the College recently qualified.

SPECIAL COURSES are held for all the University Examinations, for the Primary and Final Fellowship Examinations of the Royal College of Surgeons, and for the Membership Examination of the Royal College of Physicians.

HOSPITAL PRACTICE.—Exceptional opportunities are offered to qualified Practitioners wishing to attend the General Practice or the Practice of a Special Department of the Hospital.

A Clubs' Union, an Athletic Ground of over 13 acres, and a *Students' Hostel*, promote the recreation, health, and comfort of the Students.

For Prospectus and Particulars apply to the Dean (Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S.), who will be pleased to make arrangements for anyone wishing to see the Medical College and Dental School.

MILE END, E.

FACULTY OF MEDICAL SCIENCE.

COMPLETE COURSES OF STUDY ARE PROVIDED FOR THE PRELIMINARY AND INTERMEDIATE EXAMINATIONS OF:

(1) The University of London.
(2) The Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons; and also for
(3) The Degree in Dental Surgery (B.D.S.).
(4) The Primary Fellowship Examination of the Royal College of Surgeons.
(5) The First Professional Examination for the Licence in Dental Surgery of the Royal College of Surgeons.

The College, without in any way lengthening the duration of the Course, offers, like Oxford and Cambridge, the advantages of a broad University Education to Medical Students before they proceed with the purely clinical subjects.

Valuable Scholarships and Prizes are awarded on the results of examinations held annually.

The hostel for men students (King's College Hall, Champion Hill, S.E.5) is close to the hospital, and contains accommodation for 80 students. The hostel for women students is at 58, Queensborough Terrace, Bayswater.

For detailed prospectus of the Medical and Dental Courses and for further information apply to the Dean, Prof. R. J. S. MCDOWALL, D.Sc., M.B., Ch.B., F.R.C.P.(Edin.), or to

S. T. SHOVELTON, M.A., Secretary.

Strand, W.C.2.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE.

MARY LOUISA PRENTICE MONTGOMERY LECTURESHIP IN OPHTHALMOLOGY.

The Committee of the School of Physic, Trinity College, invite applications for a Montgomery Lecturer, for the year 1930, who may be recommended by them to the Board of Trinity College. The person nominated must be a recent graduate of a recognized Irish School of Medicine and must undertake to prosecute study or research for a period of not less than six months in such place as the Board may approve and must, during his year of office, give an account of his research in a public lecture or lectures. The remuneration will be £150. Candidates must send their applications to the Registrar of the School of Physic not later than November 1st (1929), and must state therein the work they propose to undertake and the place where they propose to carry it out. Applications should be accompanied by a statement of the applicant's qualifications and by a reprint of any published work.

THE LONDON HOSPITAL MEDICAL COLLEGE.

(University of London.)

ADVANCED MEDICINE.

A Course of Post-Graduate Instruction in Advanced Medicine suitable for candidates preparing for the M.D., M.R.C.P. Examinations will begin on Monday, October 14th.

The Course will comprise the examination of selected cases in the Wards, Ward Demonstrations, and instruction in Applied Physiology, Morbid Anatomy, Clinical Pathology, and Pathological Chemistry.

Further particulars may be obtained on application to the Dean, Professor WILLIAM WRIGHT, M.B., D.Sc., F.R.C.S., London Hospital Medical College, Mile End, E.

County Borough of Barrow-in-FURNESS.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited for the above appointment at an inclusive salary of £600 per annum.

Candidates must be fully qualified and registered medical practitioners, with experience in the diagnosis and treatment of Tuberculosis. The successful candidate will be required to devote the whole of his time to the duties of the office, to assist in the general administrative work of the Department, and in the Medical Inspection of School Children, and will be under the direction of the Medical Officer of Health.

Particulars of the duties may be obtained on application to the Medical Officer of Health, Town Hall, Barrow-in-Furness.

Applications, stating age, experience, and qualifications, and endorsed "Assistant Medical Officer," and accompanied by copies of not more than three recent testimonials, must be received at my office not later than Saturday, September 28th.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Preference will be given to candidates possessing the D.P.H.

W. A. CHISLETT, Town Clerk.

Town Hall, Barrow-in-Furness. September 5th, 1929.

County Borough and Port of GRIMSBY.

APPOINTMENT OF PART-TIME CLINICAL TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from fully qualified and registered medical men not over 45 years of age for the above post.

Candidates must have had previous Dispensary and Sanatorium experience and have held a Resident post in a general Hospital. They must also possess the D.P.H. and be able to use Ultra-violet and X-ray apparatus. Experience in surgical tuberculosis will be deemed to be an additional qualification.

The appointment is subject to the approval of the Ministry of Health. Salary £750 per annum.

The selected candidate will be required to assist the Medical Officer of Health in his routine duties when not engaged in tuberculosis work.

Form of application and conditions of appointment can be obtained from the undersigned, and should be accompanied by three recent testimonials, to reach me not later than September 30th.

JOHN W. JACKSON, Town Clerk.

Town Clerk's Office, 170, Victoria Street, Grimsby.

County Borough of Barnsley.

ASSISTANT TUBERCULOSIS OFFICER AND RESIDENT MEDICAL OFFICER.

Applications are invited for the post of Assistant Tuberculosis Officer for the Borough and Resident Medical Officer and Superintendent of the Mount Vernon Sanatorium.

Applicants must have held a resident appointment in a General Hospital.

Salary £450 per annum, rising by £25 per annum to £600, with board and residence.

Particulars of duties and form of application may be obtained from the undersigned, to whom applications, accompanied by copies of three recent testimonials, should be sent not later than September 17th.

A. D. MASON, Town Clerk.

Town Clerk's Office, Barnsley.
September 2nd, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
„ 18 „ „ „	430
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in October to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 23rd October, 1929.

Indian Research Fund ASSOCIATION.

Wanted, a trained BACTERIOLOGIST with known qualifications as a research worker to undertake research upon Cholera problems in the laboratory and field under the Indian Research Fund Association. Appointment will be made on the basis of three yearly contract subject to one year's probation. Salary Rs.1,500 per mensem, rising by Rs.100 increments to Rs.1,700 in last year of contract (equivalent at present rate of exchange to £1,340 to £1,520 p.a.) with usual departmental travelling allowance and halting allowance; salary to start from date of landing in India. Free passages out and home, first-class B.P. & O. or equivalent, at termination of contract or period of employment. Return passage also paid if first year's probation not satisfactory. Usual service conditions regarding leave, i.e., one month's leave with full pay after eleven months' service or equivalent proportion, cumulative; with usual casual leave not exceeding 15 days in the year.

Suitable man would have every prospect of renewing agreement or obtaining suitable equivalent employment.

Apply, stating qualifications and experience, with copies of relevant testimonials, to the Secretary, Indian Research Fund Association, Simla, India, from whom any further information as to qualifications most desired or on other points can be obtained.

Indian Research Fund ASSOCIATION.

Wanted for service with the Malaria Survey of India, a competent RESEARCH WORKER, medical qualifications preferred capable of undertaking independent enquiries on Malaria in the field and in the laboratory. Appointment will be made on basis of three yearly contract subject to one year's probation. Salary Rs.1,500 per mensem, rising by Rs.100 annual increments to Rs.1,700 in last year of contract (equivalent at present rate of exchange to about £1,340—£1,520 per annum), with usual departmental travelling allowance and halting allowance. Salary to start from date of landing in India. Free passages out and home, first-class B.P. & O. or equivalent, at termination of contract or period of employment; return passage also paid if first year's probation not satisfactory. Usual service conditions regarding leave, i.e., one month's leave with full pay after eleven months' service or equivalent proportion, cumulative; with usual casual leave not exceeding 15 days in the year.

Suitable man would have every prospect of renewing agreement, or obtaining suitable equivalent employment.

Apply, stating qualifications and experience, with copies of relevant testimonials, to the Secretary, Indian Research Fund Association, Simla, India, from whom any further information as to qualifications most desired or on other points can be obtained.

The Otago Hospital Board.

R. ARMSTRONG, Medical Supt.

Sept. 10th, 1929.

Borough of Swindon.

ASSISTANT TO THE MEDICAL OFFICER OF HEALTH.

The Corporation of Swindon invite applications from fully qualified medical men for the position of Assistant to the Medical Officer of Health. The principal duties will be the Medical Inspection and Treatment of School Children, and the work of Maternity and Child Welfare. Applicants not to be over 40 years of age.

The commencing salary will be £600 per annum.

The person appointed will be required to devote the whole of his time to the duties of the office, and to act under the supervision of the Medical Officer of Health.

The applicant selected for the appointment will be required to pass a medical examination and (if appointed) to contribute to the fund established under the Local Government and Other Officers Superannuation Act, 1922.

It is desirable that intending applicants should possess a Diploma in Public Health, or be in a position to obtain the same at an early date.

Excellent opportunities present themselves for gaining experience in the working of a modern Public Health Department, together with facilities for pathological research. The appointment will be terminable by three months' notice on either side.

Copies of definition of duties and forms of applications may be obtained from the Medical Officer of Health, 61, Eastcott Hill, Swindon.

Applications (upon the prescribed forms), endorsed "Assistant Medical Officer," should reach the undersigned not later than Saturday, the 21st instant.

Town Hall, Swindon. W. H. BENTLEY, Town Clerk.

September 5th, 1929.

West Middlesex Hospital, ISLEWORTH.

APPOINTMENT OF RESIDENT ASSISTANT MEDICAL SUPERINTENDENT.

The Guardians invite applications for the appointment of Resident Assistant Medical Superintendent and Assistant Medical Officer of their Warkworth House Institution and Scattered Homes, which are adjacent, from medical practitioners with previous experience in major surgery and of administration in similar Institutions.

Commencing inclusive salary £450 per annum, rising, upon approved service, on October 1st, 1930, and thereafter, annually by £50, to £600 per annum, together with residential emoluments valued for superannuation purposes at £90 per annum. All fees received are to be repaid to the Guardians.

Applications, upon forms to be obtained by forwarding a stamped addressed foolscap envelope, are to be returned to the undersigned before 10 a.m. on Tuesday, Sept. 24th.

Toolands House, 34, Twickenham Road, Isleworth, Middx. F. E. HARMSWORTH, Clerk to the Guardians

September 10th, 1929.

Whitehaven and West Cumberland Hospital, WHITEHAVEN.

(90 Beds.)

Applications, stating age, nationality, etc., together with copies of three testimonials, to be sent to the Secretary, endorsed "House Surgeon," not later than Tuesday, Sept. 10th.

R. HIGGINS, Secretary.

District Infirmary, ASHTON-UNDER-LYNE.

(General Hospital, 200 Beds, mainly Surgical.)

Wanted, a Male HOUSE SURGEON, preferably with experience of Eye work. Six months' appointment. Salary at the rate of £150 per annum, with board, residence, and laundry.

The Resident Staff comprises a Resident Surgical Officer and three House Surgeons.

Applications, with testimonials, to be sent at once to the undersigned.

FRANK OLIVER, Sept. 2nd, 1929. Gen. Supt. & Secretary.

Cumberland Infirmary, Carlisle.

HOUSE PHYSICIAN (male), required October 1st. Six months' appointment. Previous experience desirable. Salary at rate of £155 per annum, board, residence, etc. Applications, stating age, with copies of four testimonials, must be received by the undersigned by first post on Saturday, September 21st.

J. G. HOWITT, Secretary.

Northamptonshire.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Northamptonshire County Council invite applications for the appointment of Medical Officer of Health and School Medical Officer for the Administrative County of Northampton.

Applicants must be legally qualified and duly registered medical practitioners, and hold a Diploma in Sanitary Science, Public Health, or State Medicine. They must also have had previous experience in Public Health administration under a local government authority.

The salary will be at the rate of £1,100 per annum, payable monthly, together with offices, staff, stationery, and such allowances for travelling and other necessary out-of-pocket expenses as the County Council shall from time to time approve. A periodical review of salaries is made by the County Council and suitable increments of salary will be given for proved ability and satisfactory service.

The salary will be subject to a deduction of 5 per cent. per annum for superannuation in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which the County Council have adopted.

The candidate appointed will be required to pass a medical examination.

The officer appointed must reside at a place to be approved by the County Council and devote the whole of his time to the service of the Council and Education Committee; he will be responsible for the carrying out of the Public Health work now developing upon or which may hereafter devolve upon the County Council or its Committees.

The appointment is to be held subject to the provisions of the Sanitary Officers Order, 1926; and is determinable (subject to the provisions of Section 68(5) of the Housing, Town Planning, etc., Act, 1909), upon three months' notice on either side.

Further particulars, if required, may be obtained on application to the undersigned.

Applications, endorsed "Medical Officer," with not more than three recent testimonials, giving full particulars of the training, qualifications, experience, and age of the applicant, should reach the undersigned on or before Sept. 27th.

Applications and testimonials for the use of members of the Public Health, etc., Committee must be printed or typewritten, and not less than thirty copies should be supplied for this purpose.

Canvassing will disqualify.

H. A. MILLINGTON, County Hall, Northampton. Clerk to the County Council.

Middlesbrough Union.

HOLGATE HOSPITAL.

APPOINTMENT OF LADY CLERK.

The Guardians of the Middlesbrough Union invite applications for the appointment of Medical Superintendent's Lady Clerk at their Holgate Hospital, Linthorpe, Middlesbrough.

Salary £3 per week, with dinner and tea daily. Applicants must be competent shorthand typists and it will be an advantage if candidates are conversant with medical terms and the office routine of a Hospital.

Applications in candidate's own handwriting, stating age, previous experience and any special qualifications for the post, and accompanied by copies of three recent testimonials, should be sent so as to be received by me not later than Saturday, October 5th.

Poor Law Offices, Municipal Buildings, Middlesbrough. H. BILSON, Clerk to the Guardians.

September 6th, 1929.

Borough of Keighley.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified male persons, not exceeding 40 years of age, for the above appointment, at a commencing salary of £800 per annum.

The appointment will be made subject to the provisions of the Public Health (Officers) Act, 1921, and the Sanitary Officers Order, 1926, to the Superannuation Scheme adopted by the Council, and to the passing of a medical examination.

The officer appointed will be required to devote the whole of his time to the duties of the office.

Applications, on forms to be obtained from the undersigned, marked "Medical Officer," and accompanied by copies of three recent testimonials, must be delivered not later than September 25th.

Town Hall, Keighley. S. WALKER, Town Clerk.

September 2nd, 1929.

Metropolitan Borough of LEWISHAM.

ASSISTANT MEDICAL OFFICER OF HEALTH AND MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Lewisham Borough Council invite applications from duly qualified medical men for the appointment of Assistant Medical Officer of Health and Maternity and Child Welfare Medical Officer.

The salary will be at the rate of £650 per annum inclusive, rising by annual increments of £25 to £750 per annum inclusive.

The person appointed will be required to give whole-time to the duties of the office, and will be under the administrative control and supervision of the Medical Officer of Health. He will be required to live within the Borough.

The appointment is subject to the approval of the Ministry of Health and to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and also subject to three months' notice on either side to terminate the same.

Preference will be given to candidates (a) who have special experience in Maternity and Child Welfare work, and (b) those holding, in addition to other qualifications, a Diploma in Public Health.

Selected candidates will be required to undergo a medical examination.

Applications for the appointment, accompanied by copies of not more than three recent testimonials, must be made on forms to be obtained from the undersigned, and should be received here not later than 4 p.m. on Monday, September 30th.

Canvassing, directly or indirectly, is prohibited, and will disqualify.

Lewisham Town Hall, Catford, S.E.6. JOHN W. SHUTER, Town Clerk.

September 7th, 1929.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

APPOINTMENT OF ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified medical men for the position of Assistant Medical Officer.

Every applicant must be a registered medical practitioner, under 40 years of age and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of bacteriology or radiology is desirable.

Salary £350 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Monda[illegible]

August 30th, 1929.

Kettering and District General HOSPITAL. (82 Beds.)

Applications are invited for the post of JUNIOR HOUSE SURGEON. Salary £100 p.a., with board, residence, and washing. Candidates must be fully qualified and registered.

The appointment is for six months, but candidates will be eligible for re-election.

Applications, stating age, nationality, and qualifications, together with copies of three recent testimonials, to be sent immediately to the Secretary-Superintendent.

Sculcoates Union, EAST YORKSHIRE.

RESIDENT ASSISTANT MEDICAL OFFICER (Female).

The Guardians invite applications from qualified persons for the full-time appointment of Resident Assistant Medical Officer at the Institution Infirmary, Beverley Road, Hull.

Having regard to the Local Government Act, 1929, the appointment will be made for the period expiring March 31st, 1930.

Applications will be considered from persons between and including ages of 25 and 40 years only.

The number of sick inmates is about 300.

The salary will be at the rate of £300 per annum (no bonus) and board and other usual allowances (valued at £150 per annum) will be provided. There will be no fees in addition to the salary.

The Infirmary is not under separate administration. The staff comprises a Medical Officer, a Visiting Surgeon, a Superintendent Nurse, and 65 other Nurses.

Particuars of the duties will be sent on request.

Applications, setting out qualifications, dates of registration, experience, etc., together with copies of three recent testimonials, must be sent so as to be received by me not later than 10 a.m. on Monday, the 23rd instant.

Selected candidates will receive notice when and where to attend.

12, Harley St., Hull. W. BARROW, Clerk to the Guardians.

September 4th, 1929.

City of Coventry.

MEDICAL OFFICER OF HEALTH.

The Coventry City Council invite applications from qualified practitioners in Medicine, Surgery, and Midwifery, who are also holders of a Diploma in Public Health, for the position of Medical Officer of Health of the City.

A form of application (upon which full particulars are given of the conditions of appointment and the duties of the office) may be obtained from the undersigned, and all applications must be made on the prescribed form.

Age must not exceed 40. The salary will be an inclusive salary on Grade A of the Council's scale, commencing at £1,225 and rising to £1,500 in the manner stated in the conditions of appointment. The post will be a designated post under the Local Government and Other Officers Superannuation Act, 1922.

Applications must reach the undersigned not later than Saturday, October 5th.

Canvassing, direct or indirect, will be regarded as a disqualification.

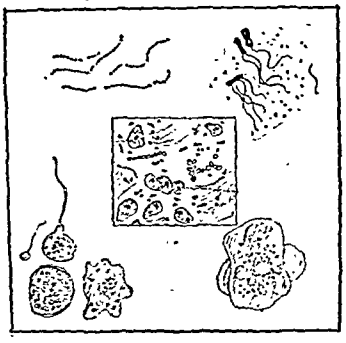
When the Colon Bacilli Revolt



WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxæmia resulting from constipation and fæcal impaction, the consequences may be grave in the extreme.

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fæcal impaction, and in certain forms of intestinal toxæmia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL Brand Compound, *the original agar-agar emulsion.*

A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* mineral Oil — Agar-Agar Emulsion (with Phenolphthalein) and has these advantages:
Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

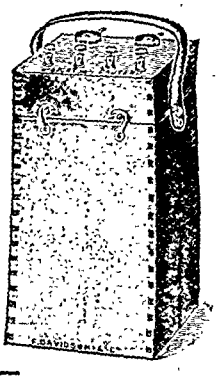
Our "Davon" Battery has been before the profession for 20 years and maintains its reputation. Many Doctors have used one for 2 years and more. *INSIST UPON HAVING THE "DAVON"* (our registered trade mark).

NEW PORTABLE SET FOR CAUTERY AND LIGHT.



No. 18C. 0 to 4 Volts.
Actual capacity 20 ampere hours.

This constitutes an achievement in the production of a highly efficient apparatus at a moderate cost.

No. 18C comprises a new pattern 4 volt glass accumulator made without plate separators and concealed rheostats for cautery and light actuated by rotating knobs on the lid. These permit of very easy and gradual adjustment. Separate terminals for cautery and light allow of both being employed at the same time.

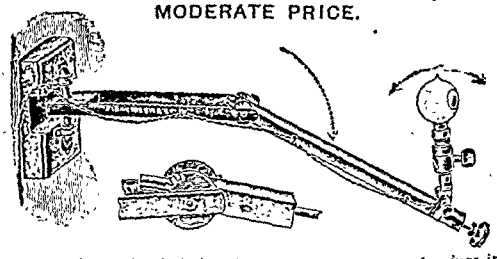
Walnut Box with strap handle.
Price ... £4 4 0.

GUTMAN'S SELF-HOLDING VAGINAL SPECULUM. (Foreign)

With electrical attachment, rheostat, and "Davon" battery.
Price ... £4 5 6

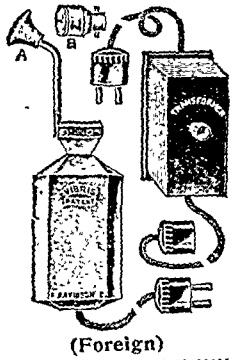
THE "DAVON" BRACKET.

Well made and serviceable at a very MODERATE PRICE.



The wall arm is of steel and rotates in very strong bearings in a horizontal radius of 90 degrees. The forearm is of nickelled brass, and can be adjusted in a vertical direction above or *below* the centre. By a slight pressure upon the ebonite knob (seen below the lamp) a clutch is caused to disengage from one of a series of teeth in the discs visible at the hinge; by releasing the pressure the clutch is self locking in the position the lamp is desired to assume. One hand only is necessary to adjust, and when not in use the lamp will fold flat to the wall.

Price without bulb £2 2 0.
Target frosted bulbs (please state voltage) each 3/6.



(Foreign)

A NEW INSTRUMENT FOR VIBRATORY PERCUSSIVE MASSAGE

WORKING ON THE PRINCIPLE OF THE ELECTRO-MAGNET.

THE "VIBRIS"

British Patent No. 289712

SUPERSEDES ENTIRELY EVERY OTHER FORM.

Special Features: Vibrations varied by pressure on "A" from the most delicate to strong. There is no internal motor. It operates direct from the house current. It is absolutely safe in anyone's hands. The "VIBRIS" is only 6 inches long and weighs but 9 ounces.

PRICES:
Without Transformer
£2 10 0
for A.C.
With Transformer
£3 5 0
for D.C.
Please state voltage, etc.

"A REAL MEDICAL INSTRUMENT"

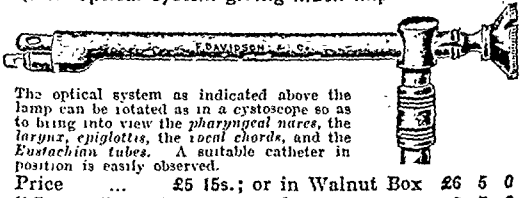
Dr. ——, Glasgow, writes: "I have used it with great success on a case of joint rheumatism."

Special Medical Discount 20%.

ELECTRIC PHARYNGOSCOPE.

(Foreign)

(New optical system giving much improved view.)



The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx*, *epiglottis*, the *vocal chords*, and the *Eustachian tubes*. A suitable catheter in position is easily observed.

WITH SUPPLEMENT.

No. 3585. SATURDAY, SEPTEMBER 21, 1929. Price 1/3

For Inflammation of Mucous Membrane

IN CORYZA, RHINITIS, PHARYNGITIS, LARYNGITIS, URETHRITIS, ETC.

NEO-PROTOSIL is a combination of silver iodide with a soluble protein base. When added to water it readily dissolves, yielding colloidal solutions which are unaffected by saline solution.

Neo-Protosil is fully as active as pure carbolic acid in germicidal effect when tested against the majority of pathogenic micro-organisms, and it is twenty times as active when tested against the gonococcus.

Even the stronger solutions of Neo-Protosil are bland and non-irritating and do not appreciably stain the skin or mucous membrane.

The therapeutic uses of Neo-Protosil depend upon the antiseptic and sedative influence exerted by solutions upon mucous surfaces and it has given good results in the treatment of inflammation of accessible mucous membranes, such as those of the ear, nose, throat and genito-urinary organs.

Neo-Protosil

A Non-irritating Colloidal-Silver Bactericide.

Issued in convenient capsules each containing 6 grams, making approximately a 5 per cent. solution when added to 2 fluid drachms of water. Supplied in bottles of 25 or 100 capsules; or as granules in bottles of 1/2 oz. or 1 oz. A sample will be sent free to any medical man on request.

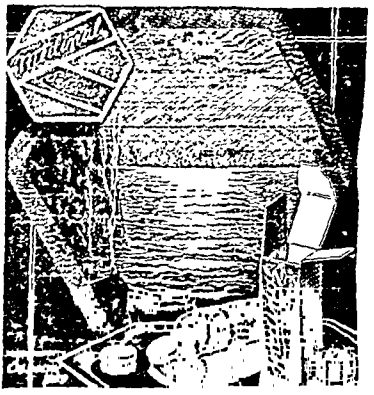
PARKE, DAVIS & CO. 50 BEAK ST., LONDON, W.1.

D

THE STANDARD HYPNOTIC

Clinical experience over a long period has demonstrated the remarkable value of

'MEDINAL' in INSOMNIA



arising from no matter what cause. The soporific effect is rapid in onset and prolonged in action, and there are absolutely no carry-over effects to be feared. The ready solubility of 'Medinal' implies quick absorption and rapid elimination.

POWDER. TABLETS (5 and 7½ grs.)
CACHETS (5 and 10 grs.)
DOSE: 5 10 grains as required.

THE SAFE ANALGESIC

It may be agreed that a safe and effective analgesic is of pronounced value in conditions of painful menstruation and

'VERAMON'

has been found remarkably satisfactory. Its action is rapid, well sustained and obviates interference with the ordinary duties of the patient. Although its pain-relieving properties are so marked, it is perfectly safe—in therapeutic doses—and its field of usefulness ranges from simple headache to inoperable carcinoma. Further, clinical reports refer to its effectiveness in the extreme pains of biliary and renal calculus and in labour pains.

TABLETS (6 grain). POWDER.
DOSE: 1-2 tablets as required.

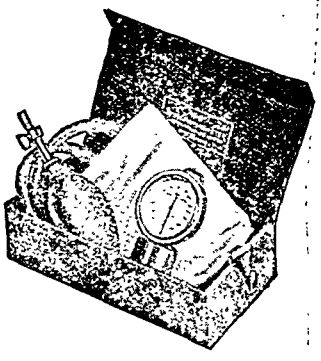
As Necessary as a Stethoscope

The present-day physician can ill afford to dispense with a sphygmomanometer as part of his visiting equipment. Many of the greatest medical minds of to-day advocate blood pressure tests as a guide to the eventual diagnosis.

The question of portability is easily solved by the S. & M. Portable type of Sphyg. as illustrated. This instrument—including Patent Arm Sleeve and Inflating Bulb with Control Valve—is contained in a leather carrying case 7 in. long, 4 in. wide by 3 in. deep.

Write for full details and prices.



Every genuine instrument bears the trade-mark "Tycos" engraved on the dial.

Obtainable from all reputable Instrument Dealers.

A SYSTEM OF

BACTERIOLOGY

IN RELATION TO MEDICINE

By Various Authors

This work is being prepared under the auspices of the Medical Research Council and published by H.M. Stationery Office. It will be issued in nine volumes, each of some 400 pages, the earliest of which (Vol. III) is now ready and the others will appear at intervals of a few months.

The aim of the System is to give a comprehensive but not encyclopædic survey of our present knowledge of bacteria and spirochætes, with special regard to their relations to the various fields of medical work. It will also include short reviews of those economic applications of bacteriology which have special interest for the medical worker.

This system of Bacteriology is the work of nearly 100 British bacteriologists, each treating the subject in which he has taken special interest. Each article represents the judgment of its author upon the present state of knowledge, based upon the published work of others and his own experience. No attempt has been made to include for historical purposes all the conflicting views of the past; only those have been selected for critical review which have seemed to the authors to have a basis of truth or some important relation to modern work. The Rt. Hon. the Earl of Balfour, K.G., O.M., F.R.S., Chairman of the Medical Research Council, contributes a general preface to the work.

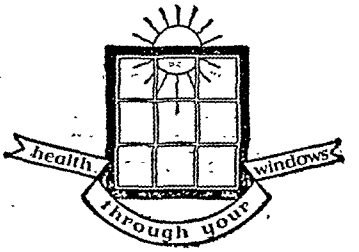
"VITA" GLASS REMOVES A HEALTH RESTRICTION

Natural Ultra-Violet Radiation in Sheltered Conditions

For five centuries windows have screened houses from wind, rain, cold and health, for ordinary glass, while it affords protection from weather, provides an impassable obstacle to the ultra-violet rays of daylight. The invention of "Vita" Glass, which gives permanent admission to those rays, enables medical practitioners to prescribe more healthful home conditions for their patients.

A recommendation to fit "Vita" Glass can prove a valuable supplementary measure in the restoration of debilitated resistance powers. Particularly is such a recommendation useful when a patient has reached the convalescent stage after a long illness, for "Vita" Glass creates conditions approximating those that obtain out of doors, but without the exposure to weather hitherto inevitable if the benefits of natural ultra-violet radiation were to be gained.

There is now no great expenditure involved which might deter a wider use of "Vita" Glass. The sum of 30/- (plus the cost of fixing) would be sufficient to cover the cost of "Vita" Glass for a window of average size in a modern house. Fuller particulars will be forwarded to any medical man who writes to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

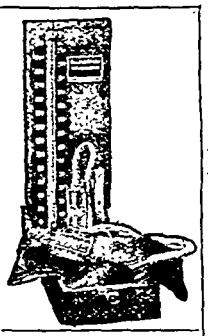


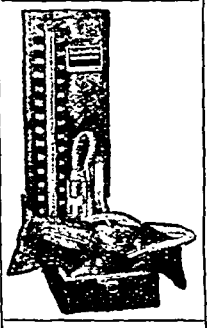
"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

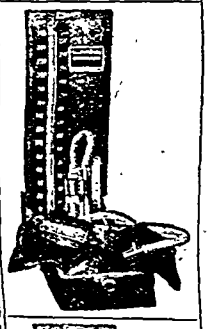
"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

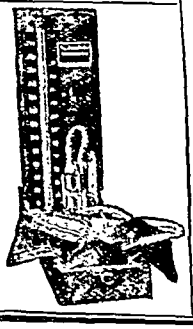
V. 222

SPECIALIZATION in this one field of endeavor—bloodpressure apparatus—has enabled us to attain in the *Lifetime Baumanometer,* the highest degree of *Accuracy—Simplicity—Permanence—Beauty*—the four chief essentials of modern bloodpressure instruments. Under these headings we list the many innovations and refinements that insure these in faithful performance to Baumanometer owners.









Scientific Accuracy

Every *Lifetime* Baumanometer is individually calibrated, scientifically accurate and GUARANTEED to remain so—accurately interchangeable glass Cartridge Tube and standardized steel reservoir—stabilized mercury column—no oscillations—no mercury spilling—minimum oxidation—readily cleanable tube and reservoir—calibrations directly on tube, white background for mercury—most easily read scale and tube and *a full unobstructed scale reading from 0 to 260 or 300 mm.—no parallax errors. A master instrument!*

Utmost Simplicity

Instantly ready for use—no adjustments, attachments, or fitting several parts together—one compact, EASILY PORTABLE unit—positive control over mercury column—equally practical for desk or out side use. *The essence of simplicity!*

Real Permanence

Glass Cartridge Tube GUARANTEED AGAINST BREAKAGE FOR YOUR LIFETIME (a written guarantee is given to every purchaser)—entire manometer unit encased in metal and *chromium-plated*—no cemented joints—no friction points—nothing to get out of order—nothing to wear out except pure gum tubing and bag and English handmade pure gum Baumanometer bulb which will last for years. *A truly lifetime apparatus!*

Well-Proportioned Beauty

Hand-rubbed solid walnut case—beautiful ivoroid scale—the result of years of specialized endeavor to perfect an instrument of correct proportion, design, and construction. *A beautiful and modern piece of equipment!*

You Couldn't Expect More—

Lifetime Baumanometer

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURE.

Typical Case.

E. H. H., aged 12 years.

Diagnosis: Fracture of the right radius and ulna.

Operation: Reduction of fracture—closed method.

Anæsthesia: Transverse infiltration block; 40 c.c. of 1 per cent. Novocain-Adrenaline solution being used.

Operation: A transverse block was immediately made at a point 5 cm. above the line of fracture. The fractures were reduced, a moulded plaster-splint was applied, and the boy allowed to return home with his mother.

NOTE.—This case is mentioned to illustrate certain points. The child's mother was a widow without funds. The child came to the surgery during usual hours on a busy afternoon. The necessity for preparing him for General Anæsthesia as well as the necessity for employing an anæsthetist or sending the child to the hospital, the amount of time required in order to carry out the necessary treatment were factors which entered into the handling of the case. Under the plan mentioned above an assistant anæsthetized the arm, the surgeon reduced the fracture, and the assistant then applied the necessary dressing. The total expenditure of time by the surgeon was less than five minutes. Furthermore, the child left the surgery travelling on his own power. From an economic standpoint the use of Local Anæsthesia in such a case presents many advantages.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Disturbances of Menstruation & the Menopause

The close association between the efficient action of the ovaries and the blood calcium index, provides a good reason for the administration of Kalzana in these cases. The chemical composition of Kalzana, calcium-sodium-lactate, is unique, and the special feature of the sodium element is that it raises the blood alkalinity, thereby promoting the retention of the calcium constituent.

Recent clinical notes state:

"I tried Kalzana on a patient who was suffering from anaemia due to disorder of menstruation (Menorrhagia). I obtained the most excellent results with it. The patient regained her original health and the menstrual period was regulated."

"I have now had three patients on Kalzana, all for menorrhagia, and it has benefited all three. One of the three also had acute dysmenorrhoea; this is cured apparently."

Kalzana is dispensed by Chemists in air-tight packets containing 50 and 100 tablets. Free from harmful by-effects and is pleasantly flavoured.

Kalzana

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available at 15/- per 1,000 tablets. Adequate samples for clinical trials, sent with pleasure, upon request.

CONVENIENT and CLEAN IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

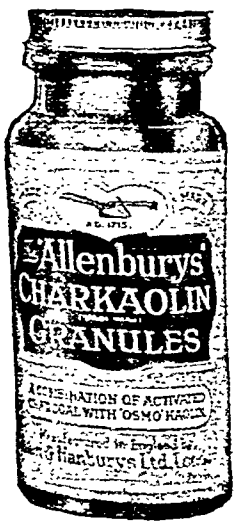
Composed of Ac. Boric., Methyl Salicyl., Ol. Menth. Pip., Thymol, Glycerin, and Kaolin.

PRICE 2/- PER 1-lb. TIN
(NOTE THE WEIGHT).

Full size free sample to any medical practitioner, in British Isles, on application by postcard.

SPECIAL DISCOUNT TO THE MEDICAL PROFESSION.

The 'Allenburys'



'CHARKAOLIN' GRANULES

A Combination of Highly Activated Charcoal with 'Osmo' Kaolin

'Charkaolin' is a new and highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin adsorbing qualities of 'Osmo' Kaolin. It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. 'Charkaolin' is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

Descriptive literature and a clinical trial sample will be sent on application.

ALLEN & HANBURYS Ltd., Bethnal Green, E.2

BOOTS PRODUCTS

Sulphostab (BOOTS)

DIOXYDIAMINOARSENOBENZOL SODIUM FORMALDEHYDE BISULPHITE

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and Co. LTD.

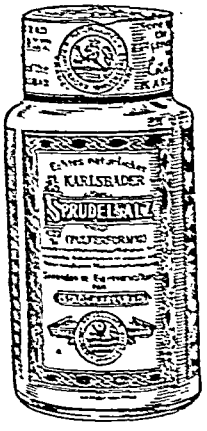
NATURAL

CARLSBAD SPRUDEL-SALT

Prepared only by the Municipality of Carlsbad from the World-famous Sprudel "Spring" at Carlsbad

(IN CRYSTALS OR POWDER)

Is the Only Genuine CARLSBAD SALT.



Largely prescribed in cases of Chronic Gastric Catarrh, Hyperaemia of the Liver, Gall-stones, Chronic Constipation, Diabetes, Renal Calculi, Gout, and Diseases of the Spleen, arising from residence in the Tropics or Malarious Districts.

Medical Practitioners should kindly note, when prescribing, to specify "Carlsbad SPRUDEL-Salt" on account of the many artificial preparations upon the market.

The wrapper round each bottle of genuine Salt bears the Signature of the Sole Agents:

INGRAM & ROYLE, LTD.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

UNG. SEDRESOL (Ferris).

A Valuable Sedative Antiseptic and Healing Ointment.

UNG. SEDRESOL is a combination of the products obtained by the destructive distillation of the wood and bark of the ***Betula alba*** in combination with Oxide of Zinc and Antiseptics.

It is specially indicated in Eczema, Psoriasis, Erysipelas,, Shingles, Erythema, Seborrhœa, Dermatitis, Pruritus Ani and Vulvæ, and in Inflammations and Eruptions of the Skin and in Burns and Scalds.

UNG. SEDRESOL is supplied to the Medical Profession at the following prices:—
¼-lb. Jars, 1/6 each; ½-lb. Jars, 3/- each; 1-lb. Jars, 5/9 each; 2-lb. Jars, 11/- each; 4-lb. Jars, 21/- each. (*Empty Jars allowed for on return.*)

SEDRESOL SOAP (Ferris).

A pure superfatted soap for the skin containing the same medication as Ung. Sedresol.
Price: 10d. per tablet, 9/6 per dozen. 30/- per dozen boxes of 3 tablets.

(The word "Sedresol" is registered under the Trade Marks Act and is the sole property of Ferris & Co., Ltd.)

FERRIS & COMPANY, Ltd.

— BRISTOL —

Wholesale and Export Druggists and Manufacturing Chemists.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Cremo - Carbonates

(Tri-Carb-Cream-Mulford)

Effective
Non-Caustic
Palatable

CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated. For the first time the well-known protectives and antacids, bismuth, magnesia, and lime are supplied as a suspension of particles of colloidal dimensions.

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth, magnesium, and calcium.

CREMO-CARBONATES is a soothing, antacid corrective and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices.

Literature and samples sent free to members of the medical profession.

HR

LIVER EXTRACT B.D.H.

In the Daily Menu

Each tube of Liver Extract B.D.H. contains the equivalent of half a pound (228 grams) of fresh raw liver—the maximum daily dose.

1—As a Soup

Add a cupful of hot (not boiling) water, milk or other suitable liquid as preferred.

2—As a Sandwich

Sprinkle dry on bread and butter with or without minced meat or fish-paste.

3—As a Savoury

Sprinkle dry on toast, biscuit or potato.

Liver Extract B.D.H. is made by a process tested and found efficient by The Medical Research Council.

OVALTINE

MALNUTRITION IN CHILDREN

Nervous and mentally unstable children are numerous, and their condition, being naturally deep rooted and inherent in the organism (as neuroses and psychoses are not of sudden onset), is difficult to remove.

From its composition and properties physicians recognize that "Ovaltine" is especially well adapted to the feeding of growing children, both in health and sickness. The mere fact that when added to a vitamin-free diet it will almost at once set up in a puny, poorly grown, and malnourished animal a growth and development normal in every respect, should in itself carry conviction.

When, however, the results of our laboratory experiments are amply and widely confirmed by the successful use of "Ovaltine" in clinics, and by prominent pediatrists throughout the world, assuredly it may be said that assurance has become doubly sure. The delicious flavour of "Ovaltine" appeals particularly to children, and they thrive upon this perfectly balanced food in a completely satisfactory way. A pamphlet, well illustrated and dealing at length with the scientific tests referred to above, will be gladly posted on request.

A liberal supply for clinical trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W.7.

"SMILER"

The Choice of a Dried Milk for Infant Feeding

The busy Medical Officer and Practitioner are often confronted with this important problem in the course of their duties. The decision must be based, above everything else, on scientific and logical considerations.

Dried milks are prepared mainly by two processes—the Spray and the Roller. In the former, the milk is subjected to a long heat treatment of pasteurisation and evaporation at temperatures varying from 45°–70°C., and finally sprayed in a blast of hot air. In the latter, the milk is subjected to a temperature of about 93°C. for 2½–5 seconds, on specially constructed rollers.

Scientific and authoritative evidence on both processes is to the effect that, while the Spray method results in a powder which is more soluble, and with the fat in a finer state of division, the curd is, like that of the original milk, still heavy and indigestible. There is some precipitation of the calcium salts, the vitamins have been partially or completely destroyed, lactic organisms, and, *ipso facto*, other organisms whose lethal temperatures are at the same, or at higher temperatures, are still present, and of economic importance, the keeping properties of the powder are limited. The Roller process yields a powder in which the fat emulsion is not so perfect, and the lactalbumen partly coagulated, but on the other hand gives a curd like that of breast milk—soft, flocculent and easily digestible. Moreover in roller powder the vitamins of the original milk are intact; it is practically sterile, and possesses far better keeping qualities.

Cow & Gate Milk Food

Cow & Gate is prepared by a special Roller process under the most scientifically controlled conditions, from the milk of the rich pasture lands of the West Country. Its value as an Infant's Food has been proved practically by the Medical Profession for over a quarter of a century.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

MAP ILLUSTRATING EXPANSION OF CHINA IN ALL DIRECTIONS UNDER THE EMPIRE-BUILDERS OF THE HAN DYNASTY.—Under the Han dynasty, which lasted 231 years, China may be said to have become a world-power. Far-reaching additions of territory were made to the empire, as may be seen from the accompanying map; overland trade was begun with India, Parthia and Mesopotamia. Buddhism now first entered China, from India, and left its mark for ever upon her institutions and her art. In the Far East itself, China's conquest of Corea led to her first knowledge of the Japanese. The period of military expansion lasted from 138-110 B.C. Internally, the Han emperors initiated a change in social policy. Lui Pang, the first of the dynasty, eased the oppressive taxation and forced labour under which the country was groaning; he relaxed many severe laws substituting for these three simple and easily understood laws against murder, bodily injury and theft. His successor, Wên Ti, refrained from building palaces and laying out parks in order that taxation might be lightened.

China achieved during Han times a position she had never before held and became known to the *outside world.*

In A.D. 166 a mission arrived in China from the West, bringing presents from an emperor who is believed to have been Marcus Aurelius.

ELIMINATION AND ACIDOSIS

HEALTHY and effective metabolism depends nearly as much on the prompt removal of final products as on a supply of oxygen and essential food elements.

The dangers of inadequate or incomplete elimination consist not only in such direct consequences of intestinal atony as the retention within the alimentary canal of unassimilable food-waste, but even more in the retention in the tissues themselves of those katabolic products which really poison the neuro-muscular and inter-neural connections throughout the body.

Here, we may suspect, is a common explanation of that depletion of alkali reserve to which many "unexplained" symptoms are largely due. Hence the great relief often afforded in states of (wrongly) so-called acidosis by regular morning draughts of Eno's "Fruit Salt." This preparation, being a combination of alkalis with fruit acids, coincidently increases the alkali reserve of the blood and, by promoting gentle intestinal peristalsis, lessens the absorption of protein decomposition compounds.

Eno's "Fruit Salt" contains
No mineral aperients (such as Epsom or Glauber Salts);
No sugar;
No artificial flavouring.

To any doctor applying for it, J. C. Eno, Ltd., will have pleasure in sending post free their monograph: "Reaction of the Body Fluids; some notes on the Physiology of the so-called Acid States," which they think may be found interesting.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

J. C. ENO LTD., 160, PICCADILLY, LONDON, W.1.

Remarks
ON
THE SYMPTOMS AND DIAGNOSIS OF PLACENTA PRAEVIA:
WITH A NOTE ON THE USE OF SUBMAMMARY SALINE.*

BY
BETHEL SOLOMONS, M.D., F.R.C.P.I., M.R.I.A.,
MASTER, ROTUNDA HOSPITAL.

THE task which has been set me to open a discussion on the symptoms and diagnosis of placenta praevia is indeed a difficult one, for the treatment depends so much on diagnosis that it is nearly as impossible to divorce these two aspects of the subject as it is to separate the Ghost from the play of *Hamlet*, or, at the present juncture, the Gaelic language from Ireland. In spite of this, the effort will be made, and if occasionally a casual remark is let fall on the subject of treatment when it is necessary during the course of the discussion on diagnosis, those who realize the difficulties of the situation will excuse; those who do not, will not notice.

NOMENCLATURE.

It is absolutely indispensable in a consideration of this subject that the nomenclature should be made very clear. It has been the custom in some textbooks to group various haemorrhages in the fourth, fifth, and sixth months under this term, and as the condition of praevia then has a very different significance from that of the true condition, it seems necessary to lay down the law that "when bleeding in the last three months of pregnancy is caused by the separation of a placenta situated either wholly or in part in the lower uterine segment, the condition is known as unavoidable haemorrhage, and the placenta is termed a placenta praevia." It seems necessary further to define accurately these last three months, and to state that the condition can only occur from the twenty-eighth week, which is the first possible period when the child *may* be deemed viable. Any haemorrhage from the formation of the placenta until the twenty-eighth week must be grouped under "miscarriage." The terms "unavoidable" and "praevia" are satisfactory in that they convey the fact that haemorrhage is "unavoidable" because of the position of the placenta, which is ("praevia") before the presenting part.

The varieties of location must *next be considered*, for often it is on this important fact that treatment depends.

We speak of: (1) Central or total placenta praevia—where the placenta covers the internal os completely; when the whole of the palpable lower segment is covered by it and when its margin cannot be reached by the finger. (2) Partial—where the internal os is partially covered—that is, there is a definite space between the margin of the placenta and the rim of the os. (3) Lateral—where the edge can be felt just above the internal os in the lower uterine segment, but the os is not covered. The term "marginal" should be removed from the literature, as we believe that the above nomenclature gives the best idea of the conditions present with a view to treatment.

It was suggested by a correspondent in a recent issue of the *British Medical Journal* that the last two should be grouped as one. This would be a very retrograde step. The practitioner must differentiate the partial from the lateral varieties. He must know that if placenta is palpable over the internal os, it may not be a total praevia. He must realize that if there is bleeding suggestive of praevia, it may be a low insertion high up—that is, a lateral insertion. Finally, a lateral insertion may not demonstrate its presence until the cervix is nearly fully dilated, while the partial shows itself long before this.

The cause of the haemorrhage and the reasons for detachment of the placenta go hand-in-hand.

1. The most likely reason for separation is that the painless contractions of Braxton Hicks, which continue during the whole pregnancy, cause a passive dilatation of a lower segment which is softer and more dilatable than normal; during the later months of pregnancy the placenta does not expand with it and must therefore become detached.

2. Disease of the placenta may occasionally be a causal factor from faulty adherence, and it is a well-known fact that the placenta may be diseased.

3. The capsular development of the placenta may prevent the attachment being as firm as usual.

Hand-in-hand with these theories are: (1) the opened placental site sinuses pouring out blood after separation; (2) *haemorrhage occurring from the circular sinus* and the intervillous spaces of the placenta.

These are the most plausible of the many theories suggested.

HISTORICAL.

There has been much discussion as to the accurate knowledge of the discovery of placenta praevia, but there seems to be little doubt that Paul Portal, in 1685, was about a hundred years in advance of other obstetricians, and was the first not only to diagnose the condition, but to be aware of its importance and dangers. He mentions in his *Pratique des Accouchements* six cases of uterine haemorrhage from the os uteri. Although treatment does not come within the scope of this communication, it is of interest to note that Portal opened the cervix and delivered. Needless to say, he had many fatal cases. Among others from whose work a knowledge has been gradually evolved are Levret and Rigby, while De Graaf, in his *De Mulierum Organis* in the seventeenth century, says, "The site of the placenta in the uterus has been described by various writers in various situations." Evidently many of these obstetricians knew that the placenta could be attached to places other than the fundus, but no practical inference was deduced. This applies particularly to Mauricean, *who punctured the membranes* and left the case to Nature for the first time. Puzos did likewise. Rigby of Notts, already mentioned, gives a very definite differential diagnosis. In fact, to Rigby must be assigned the honour of being the first to suggest a nomenclature and to make differential diagnosis between accidental and unavoidable haemorrhage, even though earlier he seemed to think that sometimes the haemorrhage arose from the vagina. Among other writers who must be mentioned in connexion with the historical aspect of the subject the names of Giffard, Roederer, and, last but not least, Smellie, cannot be omitted.

ETIOLOGY.

The most valuable factor in considering etiology is to determine if the knowledge will assist in diagnosis or prevention. The following theories must be mentioned.

1. The basal implantation theory. That the ovum after fertilization is inserted in the lower uterine segment. The placenta is basal and the clinical result is a central placenta praevia.

2. The capsularis implantation theory. That the placenta is developed in connexion with the decidua capsularis as well as with the decidua basalis. This variety determines a lateral or partial placenta.

3. Defective vascularity of the decidua may make it necessary for the placenta to spread over a large area for nourishment.

4. Inflammatory or atrophic changes may be explained in a similar manner.

5. The placenta membranacea may invade the lower segment because of its size.

These are the theories which are really worth considering, and they bear out the one great theory that there is some fault in the endometrium—a true endometritis or else a hyperplastic condition, and that this may account for the abnormality. We have several times in our practice curetted the uterus two months after the occurrence of placenta praevia and have obtained the above findings. Following the growth of healthy endometrium confinements have been normal. In other words, in the basal theory the ovum seeks healthy endometrium; in the capsularis theory the ovum must spread. There is no need to explain further the other possibilities. While we are not at all wholesale advocates of the curette, we believe it to be entirely indicated two months after a placenta praevia

* Made in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association; Manchester, 1929.

labour when the uterus has regained its pre-pregnancy tone, and that by so doing placenta praevia in future pregnancies will be avoided.

THE DANGERS OF PLACENTA PRAEVIA.

These, according to world statistics, are great for the mother and very great for the child. The mother may die from collapse following on haemorrhage, from which, if she recovers, she is so desanguinated that sepsis of a fatal nature may occur. Sepsis may also occur because of the low position of the placental sinuses. It is scarcely necessary to mention that sequelae such as menorrhagia, tendency to abort, and sterility are numerous. In addition, rupture of the cervix because of its sodden condition is said to be common.

The foetal mortality is enormous. Prematurity with a 50 per cent. death rate in the first month is the rule, and this fact must be carefully borne in mind when dealing with diagnosis with a view to treatment. Death during its passage through the birth canal is common for the infant because of interference with its oxygen supply through the placenta, or else from prolapse of the cord.

The possibility of the occurrence of placenta praevia is made very evident when it is stated that in a search of the records of the Rotunda Hospital it was found that there were 326 cases among 60,130 deliveries—that is, an incidence of 1 in 183. This incidence makes very apparent the necessity for knowledge of the subject by every general practitioner. Among these cases there were 19 deaths, a death incidence of 1 in 17. This mortality rate is far too high, and with improved technique in diagnosis and treatment I am able to report a series of 55 consecutive cases since the commencement of my Mastership without mortality. Most of the babies were premature and only 12 were born alive; 2 died before leaving the hospital, so that the prognosis for the infant is extremely bad. These statistics show clearly the necessity for deep thought when deciding on treatment of a given case.

DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS.

The occurrence of placenta praevia may be suspected in pregnancy by the history of haemorrhages at various times. A perusal of the case sheets of the hospital reveals in many instances a history of haemorrhage occurring at intervals varying from the fourth month onwards. This point may be of value, for placenta praevia may be suspected, and the patient should be kept at rest, when it may be found possible to carry her on in her pregnancy until the child is well viable.

A history of previous abortions or miscarriages is sometimes elicited, but this history has been obtained so seldom that it has but slight, if any, significance. It has been suggested that, as the patient is usually multiparous, something might be elicited from the previous labours; no such facts could be made out. On the contrary, with the exception of abortions, the previous labours had, as a rule, been without incident. Repeat toxaemias are common; placenta praevia seldom occurs more than once in a woman's life. We have little or nothing to warn us of the possibility of placenta praevia. In its silence lies danger. How, then, can we diagnose the condition? The first symptom to which our attention is drawn is fresh haemorrhage accompanied by clots. This is a most important point in diagnosis; the bleeding is extremely insidious in its onset: it may occur in sleep; it may happen while the patient is sitting talking to her friends; it may be slight and may recur, or the first haemorrhage may be so severe as to cause marked constitutional symptoms, even to the extent of a fatal issue. We have met with patients whose pulse was 80 and strong one moment, and who soon after were pulseless. The bleedings are entirely unaccompanied by pain. This severe type speaks for itself and tells us the diagnosis; the patient who has recurrent attacks of slight haemorrhage is more difficult, but her case must be diagnosed as soon as possible, for a slight first haemorrhage does not mean that the next will not kill her. In fact, generally speaking, definite diagnosis is essential; a "wait and see" policy may mean a fatal result. The infant is usually premature to some extent. A study of the records revealed the fact that there was no special week more favoured than another. At any period from twenty-eight to forty weeks the haemorrhage may commence.

Following the haemorrhage, two pints of submammary saline are given under the breasts. As this takes place during the diagnosis it must be mentioned here, even though it is a part (and a most important part) of the treatment. All practitioners should carry in their maternity bag apparatus for giving submammary saline; it is the most practical method of making up for the blood lost—in the hands of the ordinary general practitioner—and it is entirely effective. Since I have adopted this prophylactic saline method at the Rotunda I have not lost a single case. People may speak of blood transfusion and venous medication, but in the emergency practice of the general practitioner a combination is necessary which is simple, safe, and effective. Once the saline is started, its administration should, if possible, be left to an assistant. At the Rotunda the saline is prepared as follows: One pint of water is boiled with two teaspoonfuls of salt; this is kept in stock solution. When required one pint of boiling water is added; this gives the correct strength and approximately the correct temperature (about 100° F.). In practice the proprietary soloids of salt may be used. The abdomen is examined and the following facts are found: (1) that the uterus is soft and painless; (2) that the presenting part is high and unfixed, and gives the definite impression that it is sitting on something; (3) a uterine souffle is heard in the region of the hypogastrium. Some authorities have suggested that the diagnosis is now made: painless bleeding, prematurity, soft painless uterus, high presenting part, uterine souffle, clotted blood. We do not subscribe to this dictum. These cardinal facts suggest the abnormality; they do not make the diagnosis definite. We hold that the only way to make a definite diagnosis is to examine the patient by the vagina. Before making this examination the doctor should have decided on his next step, for he can at any rate have made a provisional diagnosis; the vaginal examination may cause haemorrhage, and it may be necessary to treat the case immediately the vaginal examination is concluded. In placenta praevia, more than in any other condition, must a vaginal examination be made under extreme aseptic precautions. Sepsis is more than possible, but the danger of missing the diagnosis without vaginal examination is greater than the danger of sepsis. If the cervix is closed, the low implantation may be suspected by a bogginess in one or all of the fornices. If the os is open, the placenta itself is felt. It is indeed simple to diagnose the placenta; we advise our students to familiarize themselves with the touch of a normal placenta, when the diagnosis of a praevia is simple.

An examination of the urine should be made in all instances; it will probably be found to be normal. Toxaemia is seldom an accompaniment of placenta praevia, although as an exceptional circumstance it may be so. This exception must be specially stressed; when present, it is most common in the primigravida, and the case will be a typical placenta praevia with toxaemic symptoms.

Differential Diagnosis.

There are many differential points in diagnosis when a woman bleeds in the last three months of pregnancy:

1. Accidental haemorrhage.
2. Excessive show.
3. Varicose veins in some part of the tract—for example, vulva, vagina, cervix.
4. Haemorrhoids.
5. Carcinoma of the cervix.
6. Polypus.
7. Erosion of the cervix.

In addition it may be necessary, on examining the abdomen and finding the "high head," to diagnose from: disproportion; and, on vaginal examination, from hydrocephalus, anencephalus, vasa praevia, and cervical varix.

Most of these are soon cleared up. An excessive show may always be confused with any variety of ante-partum haemorrhage; its diagnosis is made by the speedy cessation of the haemorrhage, accompanied by the absence of physical signs of placenta praevia. Varicose veins of the vulva or vagina will readily be seen; the same applies to the bleeding from haemorrhoids. Occasionally an erosion of the cervix or a polypus may bring about symptoms suggestive of placenta praevia, but the erosion and polypus are

visible through a speculum. Carcinoma of the cervix will be accompanied by history and physical signs. Occasionally one meets in a primigravida a condition of "high head" which is suggestive of disproportion. The commencement of the cardinal symptoms of placenta praevia suggests this abnormality, but a careful examination must be made to confirm the diagnosis. We have had a case lately at the Rotunda where the placenta acted as a mechanical cause of delay in labour, and this was perfectly evident at the Caesarean section operation which was indicated later. It is only necessary to draw attention to this differential point in diagnosis, and to remember that occasionally the two may occur together.

Hydrocephalus must be mentioned, for the enormously *separated fontanelles* may give the impression of a cervix with placenta protruding through. In addition the height of the head when felt by the abdomen may give a wrong impression. Anencephalus may simulate anything. Vasa praevia may suggest placenta praevia, but it is unimportant.

The condition which is most frequently mistaken for placenta praevia is accidental haemorrhage, and since the treatment for each of these conditions is very different, and as the treatment for the one is entirely unsuitable for the other, the importance of making a correct diagnosis is obvious. It is well at this stage to consider the various factors in making a diagnosis between the two.

(*a*) *Parity.* Placenta praevia is more common in the multipara than in the primigravida, but it is found in the primigravida. Accidental haemorrhage is always found in the multiparous patient.

(*b*) *Toxaemic symptoms* are nearly always present in accidental haemorrhage, and they are usually absent in placenta praevia. In spite of this assertion it is necessary to give a warning: accidental haemorrhage *may* occur without toxaemia, and severe toxaemia accompanied by placenta praevia may arise. During the past year a patient who was being carefully observed during her pregnancy developed albuminuria near the end. She was admitted to hospital, and efforts were made to overcome the toxaemia. The albuminuria never disappeared, and a week before term all symptoms of placenta praevia were present. We were dealing with a hugely fat primiparous patient with albuminuria, a one-finger cervix, and central placenta praevia. For this rare combination of circumstances there was only one treatment—Caesarean section. In this exceptional case the diagnosis was difficult. It was made without vaginal examination, and confirmed by a vaginal examination immediately before operation.

(*c*) *Period of pregnancy.* Accidental haemorrhage varies. Placenta praevia more commonly occurs as a premature birth.

(*d*) *Pains* are a usual accompaniment of accidental haemorrhage; they are always absent in placenta praevia.

(*e*) The *abdomen* is tense, and the presenting part is fixed in accidental haemorrhage; while in placenta praevia there is a flaccid abdomen with malpresentation or non-fixation of the presenting part.

(*f*) The *foetus* is dead in the majority of cases of accidental haemorrhage; it is alive at the commencement of labour in placenta praevia.

(*g*) The *haemorrhage* which occurs in accidental haemorrhage is continuous and is blood-stained serum; it has been squeezed out of the uterus like the juice from an orange. The haemorrhage in placenta praevia is fresh clotted blood, which may come in gushes and varies in amount.

Finally, in discussing differential diagnosis we must refer to a type of case occasionally encountered and already mentioned. A woman who is eight months pregnant suddenly pours blood, becomes collapsed, with imperceptible pulse and other accompanying symptoms. Does one waste time in diagnosis? No, for it is nearly certain. She is immediately given treatment for collapse, while pledgets of cotton-wool are boiled in a saucepan; these are used to stop the haemorrhage, and the absolute diagnosis is made later when the collapse symptoms have disappeared, and therefore when the patient is ready for active treatment.

Prognosis and Dangers.

The prognosis where a case has been correctly diagnosed and treated is excellent; in fact, we feel we may borrow an apt aphorism on another subject, and say "our patient should not die from placenta praevia."

There are dangers, both immediate and remote. Death from collapse following haemorrhage is possible. Death from sepsis from manipulations, low implantation, and diminished vitality must be feared. Anaemia may last for some time, and the patient should be allowed to recover thoroughly from a placenta praevia confinement before embarking on another pregnancy. Contrary to the experience of others, neither adherent placenta nor post-partum haemorrhage has been found common with our patients.

To our mind, the prognosis depends on diagnostic ability with choice and technique of treatment. Treatment does not come within the scope of this communication.

Summary.

1. It is difficult to separate diagnosis from treatment.
2. Nomenclature, both with regard to period of pregnancy and situation of placenta, is considered.
3. Rigby of Notts should be given priority in making a diagnosis between placenta praevia and accidental haemorrhage.
4. A pathological condition of the endometrium is a fruitful cause of placenta praevia. Curettage should be done before the next pregnancy.
5. The incidence of placenta praevia in 60,000 deliveries was 1 in 183, while the mortality was 1 in 17. There has been no mortality at the Rotunda Hospital in the last 55 cases.
6. Although there are others, accidental haemorrhage is the important condition to diagnose from placenta praevia. The methods of doing so are given.
7. Prophylactic submammary saline is an essential part of treatment during the diagnosis.
8. Toxaemia is not a usual accompaniment of placenta praevia; an exceptional case where it occurred is mentioned.

We shall conclude by saying that the whole paper might have been summed up in a few words as follows: That the symptoms and diagnosis of placenta praevia might be written down—an absolutely painless clotted haemorrhage, insidious in nature, some time in the last three months of pregnancy. It seemed necessary, however, to refer to some salient points in order to remind ourselves and the world that women may be saved by a careful and exhaustive diagnosis which leads to correct treatment and a satisfactory result.

THE TREATMENT OF PLACENTA PRAEVIA.*

BY

F. HAMILTON LACEY, M.D., CH.B.,

CLINICAL LECTURER IN OBSTETRICS AND GYNAECOLOGY, VICTORIA UNIVERSITY OF MANCHESTER; HONORARY SURGEON, ST. MARY'S HOSPITALS, MANCHESTER.

In considering the treatment of placenta praevia we should [illegible] common ground regarding the definition of the condition, as in well-known textbooks describing the three forms—central, lateral, and marginal, according to the position of the placenta in relation to the lower uterine segment—there is a difference in the nomenclature of the marginal and lateral varieties: the position of the placenta described by Fothergill as marginal is termed lateral by Fairbairn.

I have always used the term "lateral" for the condition in which the os is approached or partly covered by the placenta, and "marginal" when only the margin of the placenta extends into the lower uterine segment. It is often difficult when there is a history of slight haemorrhage at, say, the sixth or seventh month, followed by perhaps another slight haemorrhage within several weeks, to decide whether to temporize in the hope that the child may have a favourable chance, or whether to empty the uterus

* Read in a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929.

immediately. Since the child in these cases is usually born prematurely, even when there has been no intervention, and the proportion of stillbirths is very high, the treatment adopted should be that which gives the best maternal results; if there is a history of severe haemorrhage or recurring slight haemorrhage, the uterus should be evacuated when the mother is in good condition, so that probably severe post-partum haemorrhage, sepsis, pulmonary embolism, or other complications, might be avoided. The natural inclination is to temporize when the haemorrhage is not severe, and I, like others, was inclined to do this until I had the experience in several instances of being summoned urgently to a patient whom I had been watching for some time, to find her collapsed from sudden and severe haemorrhage.

I have taken the treatment and results of 562 cases treated during the last ten years (1919 to 1928 inclusive) at St. Mary's Hospital, Manchester; if I had omitted the last year (1928) the results would have shown a much lower maternal mortality. It is very necessary to consider a large number of cases, as in this series there was a sequence of 147 in 1925–6–7 with only one death. Of the 562, 19.2 per cent. were primiparae, and the multiparae had an average number of 4.9 children. The methods of treatment adopted were as follows.

Rupture of the Membranes.—This was carried out in 126 cases, with a maternal mortality of 3 (2.3 per cent.), and 45 per cent. of the children were stillborn. This treatment was used in the less severe cases of haemorrhage, especially when the os was slightly dilated; in the majority of these cases the placenta was marginal.

Natural Forces.—In 76 cases no active treatment was adopted, as the haemorrhage was either slight or ceased after admission to hospital, or there were marked uterine contractions; there were two maternal deaths (2.6 per cent.); stillbirths 30 per cent. The deaths were due to phthisis and mitral disease, and not to placenta praevia.

Version.—This was performed in 273 cases, with a maternal mortality of 21 (7.6 per cent.), and 81 per cent. of the children were stillborn. External version was performed in 28 cases, with a maternal mortality of 1 (3.5 per cent.). Internal version was performed in 228 cases, with a maternal mortality of 17 (7.4 per cent.); after a leg had been brought down the labour was allowed to terminate naturally. Internal version and immediate extraction was performed in 17 cases, with a maternal mortality of 3 (17.6 per cent.); one of these patients had been delivered by version before admission, and was sent into hospital on account of a ruptured uterus, which was immediately packed; she recovered.

As we see, version in one form or other was the most common form of treatment, and has in the past been most popular, as it may be carried out by anyone with moderate obstetrical knowledge and skill, but the foetal mortality is always appalling. These results show, as has so often been shown, that version with immediate extraction gives bad results—the maternal mortality in this series reaching 17.6 per cent.—since the cervix tears so readily, especially in delivering the arms and the aftercoming head, causing post-partum haemorrhage and leading to sepsis.

Breech.—There were 21 cases of breech presentation, in which a leg was brought down and labour left to terminate naturally; in this series there were no maternal deaths.

Caesarean Section.—Classical Caesarean section was performed on 33 patients. Of these, 18 were primiparae of an average age of 27 years, and most of them were in the last two weeks of pregnancy; there were 2 deaths, giving a maternal mortality of 6 per cent.; the stillbirths were 13 per cent. One of the deaths occurred in a case complicated by contracted pelvis, and the other was a severe cardiac patient, seven months pregnant, who was too ill for a general anaesthetic, so a spinal anaesthetic was administered.

Induction.—Fifteen cases were treated by induction, either in the form of a Taylor's or Champetier de Ribes's bag or by packing. In this series there were no deaths, but the stillbirths were 70 per cent.

Vulsellum; Continuous Weight.—In 11 cases the treatment, as suggested by Willett,[1] of fixing an instrument to the foetal scalp and attaching a small weight was adopted; of these the maternal mortality was *nil* and the stillbirths were 27 per cent.; it was found that a vulsellum with about 1½ lb. attached gave the best results, as a heavier weight produced injury to the scalp, whereas this weight did not produce any serious injury, and yet ended labour within a few hours.

TABLE I.—*Showing Maternal and Foetal Mortality.*

	No. of Cases.	Maternal Deaths.		Stillbirths. Per cent.
		No.	Per cent.	
Membranes ruptured	126	3	2.3	45
Natural forces	76	2	2.6	30
Version	273	21	7.6	81
External version	28	1	3.5	—
Internal version	228	17	7.4	—
Internal version and extraction	17	3	17.6	—
Breech	21	0	—	—
Caesarean section	33	2	6.0	13
Induction	15	0	—	70
Weighted vulsellum	11	0	—	27
Forceps	7	0	—	—

Although perfectly aware that I am venturing on dangerous ground, owing to the abuse of Caesarean section in the past, yet I do think that this operation might be employed a little more frequently, especially for those at or near full term with a centrally situated placenta and the os almost closed, and in elderly primiparae; of the two deaths in this series of 33 Caesarean sections, one occurred owing to severe cardiac complications when a spinal anaesthetic was employed, the cardiac condition being too bad for a general anaesthetic; the maternal mortality in Caesarean section is as low as, or lower than, in other methods, such as version, and the percentage of living children is very much greater than in version.

Frey[2] has given the results of Walthard's Clinic at Zürich, where for many years all cases of placenta praevia which required operative treatment were delivered by Caesarean section; in a series of 79 cases the maternal mortality was 1.2 per cent. Kolthauer[3] has shown that in the Women's Clinic at Bremen, of 67 cases treated by different methods the maternal mortality was 11.9 per cent. and the child mortality 61.2 per cent.; after this series Caesarean section was used in the subsequent 29 cases, resulting in a maternal mortality of 6.9 per cent. and a child mortality of 17.3 per cent. I notice that from the reports of the Edinburgh Royal Maternity and Simpson Memorial Hospital this operation is coming more into favour and is yielding very good results.

Maternal Mortality.

Of the 562 cases, 28 terminated in the death of the mother—a mortality of 4.9 per cent.; in over 60 per cent. of these fatal cases the placenta was centrally situated; 15 per cent. had been treated at home for haemorrhage, in some cases even for weeks, so that they were in a very weak condition when admitted to hospital. This shows how important it is that every woman suffering from haemorrhage during pregnancy, however slight, should be admitted immediately to a nursing home or hospital where she can be under constant supervision.

In the fatal cases the treatment was as follows.

Version	21
Membranes ruptured	3
Natural forces	2
Caesarean section	2

TABLE II.—*Causes of Death.*

Puerperal sepsis	6
Post-partum haemorrhage	5
Cardiac complications	2
Phthisis	1
Pulmonary embolism	1
Moribund on admission and died undelivered	7

Other deaths were due to the condition of collapse produced by the ante-partum haemorrhage.

In the *Rotunda Hospital Reports*[1] 1918-27 (nine years) there were 124 cases, with a mortality of 7.3 per cent. Hitschmann[2] gives the following figures: Döderlein 19 per cent., Kernig 18.2 per cent., Mende 15 per cent., Lefebre 19.3 per cent., and Charlaies 15.5 per cent.

Summary.

1. Placenta praevia is one of the most dangerous complications of childbirth.

2. Haemorrhage is a prominent feature, and often there is a history of previous recurring haemorrhage.

3. Since haemorrhage, shock, and sepsis are the commonest causes of death, it is better to empty the uterus soon when the patient is in good condition, rather than attempt to temporize.

4. Central placentä praevia has the greatest maternal and foetal mortality, and there is scope for a slightly higher proportion of Caesarean sections in this type of case, especially when the foetus is alive and near full term.

5. Of the children, 75 per cent. were premature, so that the foetal mortality was high, no matter what treatment was adopted.

6. Careful ante-natal supervision should reduce considerably both maternal and foetal mortality.

7. Experience of Willett's treatment was limited, but it has given good results when used.

OPERATIVE TREATMENT IN TUBERCULOSIS OF THE LARGER JOINTS.*

BY

G. R. GIRDLESTONE, M.B., F.R.C.S.,

HONORARY SURGEON, WINGFIELD ORTHOPAEDIC HOSPITAL, OXFORD.

PART I.

SCOPE.

OUR subject is of the utmost importance to all who have to deal with "surgical tuberculosis," and is therefore bound to raise questions of great interest to the practitioner as well as to the orthopaedic surgeon. I appreciate very much the honour of opening the discussion. First I sought guidance on the interpretation of the term "larger" joints, and was told that the hip, knee, ankle, shoulder, elbow, and sacro-iliac joints were inside and the spine outside the term.

Then I noted that we are limited to operations "in the treatment of tuberculosis," and I would suggest that while diagnostic operations are so intimately concerned with treatment that they can rightly be reviewed in passing, operations for the correction of deformities left by tuberculosis, or operations designed to restore movement to fixed and soundly healed joints, must be excluded. We have today, therefore, no concern with operations other than those helpful in the treatment of unhealed tuberculosis. Surgery may be required for the *complication* of pyogenic infection, but I think that is another story, to be mentioned rather than discussed here, for we shall have fully enough to do if we concentrate on uncomplicated tuberculosis.

We are now at a critical time—conservative treatment in open-air hospitals has become well accredited, for its immediate *results* are known to be good. We must be careful lest we allow good "results" to become bad "end-results." So-called "results" merely represent an interim report in the hospital records. Our main concern, and the true test of our work, is the end-result—the lasting health and activity of the patient, or the reverse. Alan D. Smith and W. H. Watters, writing in the *Journal of the American Medical Association* for January 21st, 1928, give the following figures:

"1. Of 208 patients treated for tuberculosis of the hip at the Country Branch of the New York Orthopaedic Dispensary and Hospital from 1904 to 1921, forty-six, or 22 per cent., were found to have wrong diagnoses. We believe that such mistakes are inevitable unless the diagnosis is established by aspiration and guinea-pig inoculation, or by exploratory operation.

"2. Thirty-six patients, or 24 per cent. of 150 cases, followed for three years or more, died, the majority from tuberculosis.

"3. Seventy-one cases, or 47 per cent., still were active when last examined.

"4. Forty-one cases, 27 per cent., were quiescent with little or no motion and with some degree of deformity.

"5. Only two patients were free from symptoms and had a useful range of motion."

There is no reason to suppose that these figures are representative. For "end-results" depend on several factors which vary in different countries and different clinics. "End-results" depend partly on (1) the type and (2) the period of treatment in hospital, and partly on the environmental care afterwards. At the Wingfield Orthopaedic Hospital, Oxford, we have been able to take such care of the environment of our patients after they leave hospital, and to see them so regularly, and to admit them again promptly if necessary, that I think we can, in the great majority of cases, achieve healing, both of the joint and of the lymphatic tuberculosis. But as regards both phases of the infection we have had failures, and it is from the failures that we have most to learn.

Now we cannot afford to allow open air and rest to become discredited; they are fundamental needs, and cannot be replaced. Therefore we must learn to make our end-results come into line with our results. And here we make contact with our subject; for surgery has a big part to play in the stabilization of results. Big but limited. It is to discuss that part, its limits and its importance, its successes, its difficulties, and its failures, that we are met.

REVIEW OF SURGICAL TUBERCULOSIS.

With added experience we must again face the question, "When, if ever, is surgical tuberculosis properly surgical?" But before we begin to answer it, it is well to look squarely at the disease we are fighting and to review critically the parts that can be played by various operative (and non-operative) methods in its treatment.

Now I said in a paper read at the Provincial Meeting of the Tuberculosis Society at Cambridge on April 11th, 1924:

"Tuberculous disease of a joint or a bone is serious enough, but it is a weed with a very deep root; you may pluck the head, but the root will not come with it. A bone focus is a proof of established tuberculous infection of the body; but even this is not all, for the new focus is tangible evidence that the invasion of the body is advancing."

I feel now that the metaphor was partially misleading, for I have become convinced that the seeds of dissemination lie in the root of the disease and not in its flower. No doubt then, as now, I was preaching to the converted, but it is well to reassert this basic truth over and over again until the whole profession absorbs it. The family doctor knows the true facts, the orthopaedic surgeon is learning them, but in the general hospitals, with the relatively early discharge of patients which is necessary, the slow evolution of surgical tuberculosis cannot be watched.

On the other hand, the experience of surgical tuberculosis one gets on the staff of a hospital such as the Wingfield has all the makings of a scientific experiment on a large scale; for one sees the cases in our scattered out-patient departments before their hospital period, and lives surrounded by them, and in touch with them even after their discharge. It is a living and lasting experiment, and one learns more and more as the years pass. The experiment is characterized not only by the large number of cases, but by their unlimited variety in age, type, and environment. I am being led to a conception of the disease which has points that may be new and are, I think, valuable. Certainly they concern intimately to-day's subject.

In the second part of this paper I hope to give some of the findings of the experiment. For my present purpose I must anticipate them and pick out one striking point. In most of the patients in whom new lesions occurred, not as a result of the original bacillary shower, but at a later stage—that is, during or after hospital treatment—the joint lesion has at the time of the new development been removed or arrested, and in the latter there have been no signs of activity or reactivity in the joint lesion preceding or at the time of the development of the new lesion. This is a clear indication that the bacillaemic

* Read in opening a discussion in the Section of Orthopaedics at the Annual Meeting of the British Medical Association, Manchester, 1929.

shower can, and usually does, come from somewhere other than the joint lesion. The question comes to one's mind: *Does a bacillaemic shower ever arise from a joint lesion—and indeed can it do so?—or is it always the result of lymphatic tuberculosis?* Bacillaemic showers are proved to be a frequent occurrence in experimental animal tuberculosis; by analogy they occur in man. How can bacilli get into the blood? Only through lymph channels or direct into veins (arteries, of course, are readier to give than to receive).

Now tubercle bacilli in bone and joint foci are found in two places: (1) with ease and in considerable numbers in caseous debris; and (2) in small numbers and often with great difficulty in the granuloma, and generally in the centre of infiltrated and more or less necrotic areas quite out of touch with any lymph channel or blood vessel.

It appears impracticable for the tubercle bacilli in a chronic granuloma to pass by any channel into the blood stream. Probably only in very active fungating and extending lesions do tubercle bacilli ever reach the blood stream from a lesion developing from a bone or joint focus, and, if they ever do, probably very rarely and in very small numbers.

Now in our work activity occurs only at an early stage or in very rare cases of patients who offer no effective resistance to tuberculosis. Those of us who have done an early arthropsy and a subsequent excision know how quickly and to what a remarkable degree the early hot active inflammation is subdued. It is clear that the bacilli in the later stage cannot reach the blood directly, but it is just possible that they might reach the lymph channels, the regional glands, and eventually the blood. Apparently they do not, for the regional lymph glands to which the joint drains are never secondarily enlarged. Besides, granulation tissue is Nature's method of corking all channels (blood and lymph) against bacterial invasion. In a septic wound we feel safe from septicaemic penetration of bacteria when granulations cover the raw surface.

Do the bacilli, then, come only from the lymphatic tuberculosis?

First, we know already that bone and joint foci are metastatic from the glands—are the result of a shower from the glands—that alone is a proof of lymphatic responsibility.

Secondly, the lymph glands are filters, in the course of the current which flows ever toward the blood stream.

Thirdly, when the mediastinal and retroperitoneal glands are tuberculous the debris does not find its way to the surface of the body. Altogether it seems evident that debris rich in tubercle bacilli is carried along with the natural flow through the lymph vessels and the thoracic duct into the blood stream.

Tuberculosis of the glands appears, then, to be the great, if not the sole, source of tubercle bacillaemia. Bone and joint lesions, on the other hand, are secondary or metastatic lesions, and they appear to be "end" lesions, closed, "blind," or "static," and in themselves only dangerous as sources of toxaemia, or by their direct extension, or infections; not as potential mothers of further metastatic lesions.

Unfortunately the lymphatic lesion is out of reach, out of sight, and too often out of mind; and an active unarrested focus in a gland left after the joint lesion has healed is, I believe, a far greater danger to the patient than an unarrested focus in a joint.

THE FIELD FOR SURGERY.

Operation can remove the joint focus, or result in a synostosis which protects it from strain, but the operations we are discussing cannot have any direct bearing on the deep-seated glands. Patients in whom the tuberculosis has been carried from glands to a large joint suffer danger to the joint itself, and danger to life. To save the joint perfectly intact means exceedingly early provisional diagnosis and immediate treatment, and sufficient long-continued general treatment. In most such cases a certain diagnosis cannot at the present day be made, and they cannot appear as definitely tuberculous in statistics. (Nevertheless the patient so treated is glad of the free use of his joint.) In other cases where the lesion is extra-articular (for example, neck of femur) the joint can often be saved from infection sufficiently heavy as to overcome the joint's resistance.

Now for the dangers to life:

Danger No. 1.—Persistent joint disease, with long-continued toxaemia, secondary infection, lardaceous disease, and only a very gradual and long-delayed danger to life.

Danger No. 2.—Persistent lymphatic disease with frequent bacillary showers, and a constant danger of new metastatic lesions, including meningitis and miliary tuberculosis. The sword of Damocles—a much more threatening danger.

Our operations concern Danger No. 1. Either we remove the lesion by excision or amputation, or we promote and protect its healing by extra-articular arthrodesis. These operations do not save the joint, for they fix it; nor the patient's life, for the glands remain a potent source of danger. This may seem to belittle the importance of surgery. Not so. It is true that we must depend on general treatment to heal the glands, but it is not true that we can rely on an equal healing of the joint. For to the joint the vastly important factor of mechanical strain is added. And it is essential that the profession should recognize that without operation we cannot bring about a *safe and permanent cure* of most major tuberculous joint lesions in adolescents and adults. This may seem a statement directly contrary to the wonderful "results" obtained by all our open-air hospitals. So it is. But not to the true end-results. The "results" of such hospital treatment appear delightful, but the "end-results" can be very disheartening. A granulomatous lesion which at the end of hospital treatment was sound to Thomas's tests repeated week by week will often prove unsound to the wear and tear of the subsequent years.

From the mass of cases which come to us we can distinguish two very different types:

1. Patients in whom the joint lesion is still grumbling, though the gland focus has apparently long ago healed. These are cases in which the general resistance is sufficient for healing (and the glands have healed), but this important factor of mechanical strain persistently prevents the lesion from healing. In such the problem does seem a local one, and its complete solution may well lie in operation, whether radical, or, when radical operation is impracticable or appears unnecessary, extra-articular arthrodesis. This group mainly concerns adolescents or adults with long histories.

2. A larger group of patients in whom the joint lesion is a sign of lowered general resistance to tuberculosis. These are cases with short histories, multiple lesions, recurrences, or new lesions. In such cases operation is *not yet* indicated. The lesion is almost certainly bacillaemic, and everything must give way to physical rest and metabolic activation. Many cases fall between these two groups.

General treatment requires time, so does post-operative fixation. Naturally one wants the sentences to run concurrently so far as possible. Probably general treatment should always be given a start—in adults of some months, and in children of some years. It is possible that one should always wait until one has a number of negative results from blood culture *in vitro* or by guinea-pig inoculation. The value of such tests is a point which is now under investigation at the Wingfield Hospital. Certainly showers of bacilli should have ceased to issue from the lymphatic system into the blood before the patient is allowed to pass from good to poor environment. Whether one should wait to operate until such a stage is reached depends on several variables. Partly it depends upon whether the operation is radical or conservative, also on the general trend of the patient's health, time, and circumstances.

The view has been expressed that a major lesion—for example, a tuberculous epididymis—should not be removed because its value as a source of tuberculin is thereby lost, and the specific reaction of the whole body to tuberculosis is thus lessened. It is, I suppose, a matter of the optimum dosage in each case. My own view is that the smaller and the less active the lesion in the patient, the quicker and sounder he heals under the best environment. And I would suggest that with the metastatic source of toxaemia gone there is more than enough left to promote reaction: for the source of the bacillaemic showers remains. I think the argument for retaining the metastatic lesion is based on misleading figures in which comparison is made between

cases treated radically, and for that (illogical) reason sent out sooner, and those treated without operation. The longer period of general treatment necessitated by the retention of the metastatic focus would naturally lead in a significant proportion of cases to more advanced healing of the primary focus. The same length of general treatment *after* removal of the lesion would, in my opinion, be likely to prove even more effective. Comparisons can only be fair when an equal period of general treatment has been given to both groups.

I would suggest, then, that the first and fundamental principle is to provide general conservative environmental treatment good enough, and for long enough, to heal the lymphatic tuberculosis; that the first indication of such healing is the total disappearance, to clinical and possibly to laboratory tests, of signs and symptoms of bacillaemia; and that general treatment should be prolonged for at least a year after this indication has been reached.

Then I would say that operation is often also a fundamental need to remove a focus that is causing persistent harmful toxaemia, that is unlikely to heal at all, or at least not sufficiently soundly and strongly as to stand safely the mechanical strains to which it will be subjected. Sound healing of a joint is not enough. The tissues of which it is composed must also be sufficiently thick and stout and strong, and must connect surfaces suitably adapted. Where that is impossible without operation the surgeon must be prepared to strengthen the foundations or buttress the building, or do both.

The part the surgeon can play in the treatment of tuberculous joints is:

1. To remove a tuberculous focus metastatic in origin, and a potent source of toxaemia.
2. To buttress or rebuild a part of the skeleton which cannot otherwise safely carry the strains it will have to bear.

He operates at a time so chosen as:

1. To interfere least with the improvement of his patient's vitality—indeed, in some middle-aged or old patients radical measures are necessary in order to make that improvement possible.
2. To supply him with materials which will answer his needs (this applies to buttress building).

Radical operations may have to be done comparatively early (to save life and limb in the middle-aged or old); extra-articular arthrodesis is best done later.

A Conception of Bone and Joint Tuberculosis.

A truly balanced view of lymphatic and metastatic tuberculosis is the only sound foundation of our discussion. I put forward the following conception of bone and joint tuberculosis, in two statements, with the reasons that have led me to these conclusions.

A.—Lymphatic tuberculosis is *open* to the blood—that is, it is *bacillaemic*.

I. Tuberculous glands lead to bacillaemic showers. This is clear because:

1. Metastases occur when glands are the only pre-existing lesion.
2. It is clearly the glands and not the joint lesion that have caused new lesions in those of my cases in which the joint lesion has been previously excised or amputated.

II. Bacillaemia in active tuberculosis is frequent. This is probable:

1. On the analogy with the proved occurrence of this in animal experiments.
2. Because tubercles of different ages can be demonstrated post mortem.
3. Because of the clinical experience that trauma is associated with bone tuberculosis, and the explanation lying in the coincidence of local lowered resistance with a bacillary shower.

III. Glands are likely to cause bacillaemia. Because:

1. If they break down internally the debris would follow the natural flow through the lymph channels into the thoracic duct and so into the blood stream.
2. It seems likely that this is a common way of disposal of the debris of mediastinal and retroperitoneal lymphatic tuberculosis. Certainly an unpleasant idea, but in a sense reassuring as to the powers of our blood and vascular tissues.

B.—Bone and joint tuberculosis is *closed* to the blood—that is, it is merely *toxaemic*.

I. In granulomata tubercle bacilli are only found at the centre, and far from any vascular channel. The bacilli are found in caseous material, in pus, in giant cells, and at the very core of densely infiltrated areas.

II. The bacilli appear far out of contact with lymph channels (unless the granuloma is split open by force). Further, it is my experience that one *never finds the regional glands to which a tuberculous bone or joint drains enlarged or showing any signs of infection with tuberculosis*. This in itself goes far to prove the closed nature of these lesions.

III. In my experience of very prolonged cases where the mechanical factor seems to have kept a joint grumbling long after the general disease has been healed, new metastatic lesions do not occur despite activity of the joint disease, nor after radical treatment followed by only short general treatment.

If these statements present a truly balanced view of the disease with which we have to deal the indications and the scope for surgery can be examined clearly and reasonably assessed.

PART II.

General Indications for Operation.

In order to give subsequent speakers something to bite upon I am stating very briefly my own views as to the general indications for operation.

For Diagnosis.

Arthropsy is indicated when the diagnosis cannot otherwise be made.

Time.—At the earliest moment, for in doubtful cases good diagnostic material is not easily come by; and the better and longer the treatment the more the granuloma retires into its shell.

For Treatment.

(*a*) *Adults.*

Indication.—Radical operation is the rule.

Time.—As soon as the patient's general condition is on the mend.

Type.—Excision and arthrodesis.

Exceptions.—(1) For sacro-iliac only extra-articular arthrodesis.* (2) For the hip add also extra-articular buttressing. (3) For the ankle, astragalectomy or amputation. (4) When amputation is indicated—for example, many cases of tuberculous hip, knee, or ankle, over middle age.

(*b*) *Children.*

Indication.—Whenever sufficient damage has been done to the joint to make movement incompatible with permanent safety from relapse (or mechanical arthritis).

Exceptions.—Those cases in which there is little granulomatous tissue and in which the surfaces are well adapted.

Time.—After more than one year of treatment, when recalcification is shown on radiograms, and only when the patient is, or becomes, over 10 years of age.

Type.

Sacro-iliac.—Extra-articular reinforcement (Verrall).

Hip.—Ordinarily extra-articular arthrodesis, but when the granulomatous tissue is massive and likely to prevent effective extra-articular arthrodesis (either by leading to absorption of the graft or by giving no firm fulcrum to aid the graft in bearing strain), excision should be added.

Knee.—Restricted excision and arthrodesis. The knee is very slow to heal and very liable to recrudescence, therefore often requires arthrodesis. It is an accessible joint with good big surfaces. Its drawback is the proximity of the two growth discs; therefore the excision must be superficial, and long grafts are quite unsuitable. Further, unless the limb is well protected during the years of growth distortion is likely from the application of strains quite different from those which the metaphyseal bone is prepared to expect.

Ankle.—An individual problem. I think unsettled, except that where the lesion appears to be confined to the astragalus it should be removed. I have had few cases in children, and all these have been treated conservatively.

Shoulder.—Excision and arthrodesis.

Elbow.—Operation not indicated.

In addition: Drainage operations for pyogenic infection of tuberculous joints are sometimes required. For the hip I use a method of transverse incision and wide transverse exsection

* I use a double Verrall graft. There are ... of Smith Petersen's method in tuberculosis, (1) graft in the midst of the infected joint, (2) ... sarily composed of decalcified bone, and (3) ... its recolonization on the intoxicated cells of ...

of muscles, with suture of the skin edges deep down close to the joint; and with most satisfactory results. This I described in *The Robert Jones Birthday Volume*.

PART III.

RESULTS OF OPERATION.

With regard to results I think it will be most helpful if I briefly summarize my experiences.

DIAGNOSIS.

*Arthropsy.**—Certain bacteriological or histological diagnosis is most needed in those very early cases, clinically synovial, which otherwise cannot be identified with certainty. Unfortunately in my experience we have had a number of such cases in which in the specimen of synovia removed tubercle bacilli have not been found either by a prolonged microscopic search or by inoculating a guinea-pig; in these the histological diagnosis has often been non-committal.

TREATMENT.

Hip.

Adults.—I have recently published my views and experiences of hip operations.† In general, I would say that the difficulties lie less in the technique than in the human materials. Operations which are most satisfactory in cases where the morbid anatomy is similar but non-tuberculous often fail where the bones are decalcified and devitalized by tuberculosis. This is particularly true of grafting operations. At present I feel that the solution lies in early radical excision and late grafting. And in certain types and older ages I think amputation is indicated.

Children.—Of those treated by excision and arthrodesis none have been done long enough for a final report. I am finding it sometimes necessary as a result of much granulomatous tissue, but always as part of, or preliminary to, extra-articular arthrodesis. In those treated by extra-articular arthrodesis I have had about an equal number of satisfactory results and of failures, from absorption at the middle of the graft, due to the non-recolonization of the graft, or failure in obtaining a firm hold at one or other end. There have been no cases of sepsis, sinus formation, or sequestration. The graft has to pass close to the granuloma, and is therefore liable to become infected itself, or to fail to take hold or thicken on account of lack of initiative shown by the devitalized bone cells of the neighbourhood. The difficulties in obtaining a really effective arthrodesis may be great, but the indications are at least correspondingly strong. The hip shares with the knee an increasing notoriety for grumbling persistence and recrudescence, and has long possessed a unique name for deformation, insidious and malign. It adducts and flexes, and nothing but synostosis will stop it.

Knee.

Adults.—Local result uniformly good. End result: new lesions in other parts of the body have developed in several cases. That is to be put down to failure in general treatment. For severe septic infection of tuberculosis of the knee in adults I believe in amputation, not excision. On one occasion such a knee was excised by another surgeon—widespread sepsis, pyaemia, late amputation, and death followed.

Children.—None operated on. I have recently seen a girl of 19 whose knee had been excised in 1921. She has 7 inches of shortening! The lower epiphysis of the femur had been damaged by the surgeon and growth had ceased. I am still keeping the tuberculous knees of children in callipers, but I have become convinced that excision in children older than 10 with much articular damage may well prove right.

Ankle.

Adults.—Mainly treated by conservative measures. Operations only two astragalectomies, one of these done elsewhere. The local results have been good, but only two cases have been treated, one by Mr. Joyce at the Wingfield Orthopaedic Hospital, the other elsewhere.

Children.—None operated on.

Shoulder.

Adults.—I have only excised one tuberculous shoulder. The local result was excellent, but a year later generalized tuberculosis developed and the patient died.

Children.—None operated on.

Elbow.

Adults.—I have excised only one. The local result was good, but bony ankylosis has been delayed.

In Part II I made my suggestions definite—to invite criticism, and brief—to invite fuller and better statement. Further, I would add the warning that generalizations such as these are only general guides, and cannot be applied to any single patient, for each needs personal consideration.

* On this subject see an article on joint disease by R. K. Ghormley in *The Journal of Bone and Joint Surgery*, vol. viii, No. 4, October, 1926.

THREE HUNDRED CASES OF TUBERCULOSIS OF THE HIP-JOINT:

THEIR LATE END-RESULTS, AFTER AN AVERAGE PERIOD OF SIX YEARS AND NINE MONTHS.

BY

C. LEE PATTISON, M.B., B.S.,

MEDICAL SUPERINTENDENT, KING EDWARD VII HOSPITAL; SURGICAL TUBERCULOSIS OFFICER TO THE CITY OF SHEFFIELD; HONORARY CONSULTING SURGEON TO THE ROTHERHAM CORPORATION (TUBERCULOSIS DEPARTMENT).

USUALLY the accumulation of statistics gathered from clinical data is of little value. Nevertheless, there are times in the life of a surgeon when he is impelled to review the end-results of the treatment he has employed, hoping to encourage himself by finding that his efforts have met with success, and also wishing, by examining his failures, to find their cause and so, if possible, improve his future patients' chances.

It is with these ends in view that the study of the first 300 cases of tuberculosis of the hip-joint treated in the King Edward VII Hospital, Sheffield, has been undertaken; only those cases are included which have been re-examined personally by the author at least two years after, and an average period of six years and nine months after discharge from the hospital.

Girdlestone[1] has written: "The diagnosis of tuberculous hip disease rests on probabilities until either destruction has advanced to such a degree as makes the radiogram evidential, or abscess formation renders a conclusive test possible in the finding of tubercle bacilli."

The first difficulty, then, was to be sure of the diagnosis; in many cases tuberculosis of the hip was confirmed by radiographic or bacteriological means. This eliminated three of the other common conditions which may be mistaken for it—namely, pseudo-coxalgia, coxa vara, and infection with pyogenic organisms (usually the staphylococcus). The remaining common type of arthritis of the hip-joint is the so-called "transient arthritis," which is due to toxins from a local focus of inflammation. It is impossible to be sure in all cases that patients with apparently early tuberculosis of the hip are not in reality suffering from this affection, and it is almost certain that some patients with this condition have been included, especially in the group of cases in which recovery was complete. However, every effort has been made to eliminate such patients by excluding all those in which the symptoms disappeared permanently with one month's treatment. Apart from taking care that the above conditions were observed, no selection of cases has been made.

THE TREATMENT EMPLOYED.

The usual methods for improving the general health of the patients were used, and included nursing in the open air, real and artificial heliotherapy, and a generous but simple diet containing abundance of foods with high vitamin A and D content.

The local lesions were dealt with by those conservative methods of treatment first used so successfully in this country by Sir Henry Gauvain, together with various modifications on the lines advocated by Sir Robert Jones, Girdlestone, and others. Briefly the methods employed may be described as follows.

1. *Acute Stage with Active Progressive Disease.*

The principles underlying treatment at this stage are immobilization in bed, with traction to counteract muscle spasm. The ordinary weight-extension with pulley, the Pyrford frame described by Perkins,[2] and other forms of fixed extension were used in the treatment of the patients under discussion, according to the degree of activity of the disease and amount of deformity. Traction was maintained in one of these ways until the spasm of the muscles had disappeared and until deformity had been corrected as far as possible.

2. *Transition Stage.*

After deciding by clinical and radiographic examination whether a movable or a fixed joint would be the probable end-result, one of two different forms of treatment was adopted. In the former instance weight-extension was

continued for a period of three to six months; the patients were then allowed to lie in bed without retentive apparatus, and if movement continued to increase or was not diminished were considered to have passed into the convalescent stage. If, on the other hand, ankylosis or imperfect mobility were probable, the hip was fixed in plaster-of-Paris until as complete ankylosis as possible had taken place. In this connexion it is important to note that a double hip plaster, with a long spica on the affected and a short one on the sound limb, should be used: if this be not done there is a tendency for the pelvis to tilt even in a well-applied plaster, with subsequent adduction deformity. This will be referred to again later. If the adduction and flexion of the limb could not be corrected during the first stage, recently it has been my practice to apply the plaster under an anaesthetic, when the deformity was easily corrected, in most instances without the application of any force.

Experience is the only guide as to when it is safe to allow the patient up with crutches and patten, and also as to when he may be permitted to replace the complete fixation of plaster by the less marked protection afforded by celluloid or other splints.

3. *Convalescent Stage.*

Patients were usually discharged from hospital at the beginning of this stage, and usually went home wearing a celluloid hip spica like those made at Alton,[3] and using crutches and patten. They were examined at intervals as appeared necessary. After a period varying from six to eighteen months the splint was discarded, and later still the patten and then the crutches were given up.

Results.

The results obtained fall into four groups.

1. Those patients in whom there was a perfect functional result, with an almost completely full range of movement, no shortening, and no sign of disease.
2. Patients with quiescent disease, which was apparently arrested, but who, through shortening or fixation of the limb, were left with a certain amount of deformity and disability.
3. Patients in whom the disease became active again.
4. Patients who died or became worse in spite of treatment.

1. *Patients with no sign of disease:*

Number	167
Examined after discharge from hospital ...	65.5 months*
Average duration of hospital treatment ...	367 days
Average period with splints after discharge	10.8 months
Number working at present	40

*Average.

2. *Patients with arrested disease but some disability:*

Number	97
Examined after discharge (average period)...	85 months
Average duration hospital treatment... ...	708 days
Average period with splints after discharge	46 months
Number working at present	29

The amount of disability in these patients may be gauged as follows:

Limping badly	44
Shortening of over 1 inch	47
Some adduction	41
Some abduction	33

It was, of course, the "adducted hips" which limped most, and it is thought that if the precautions (1) of fixing both hips in plaster, (2) of correcting adduction under an anaesthetic and then applying plaster, as suggested above, be more often taken, this deformity, with its consequent limp, will not be found so frequently.

3. *Patients with recurrence of disease:*

Number	28
Recurrence occurred after discharge ...	52.8 months
Recurrence while still using splint, etc. ...	20
Average duration hospital treatment... ...	531 days
No sign of fresh recurrence after average of two years from second discharge	14

4. *Deaths and hopeless cases:*

Number	13

A NOTE ON TUMOURS OF ENDOCRINE GLANDS.*

BY

F. PARKES WEBER, M.D., F.R.C.P.

It is becoming more and more probable that a neoplasm (benignant—or malignant, of the nature of a sarcoma or carcinoma) may arise from any kind of living cell in the body, at any immature or mature stage of its development, if the necessary (but only partly known or surmised) conditions are present. The cells of the neoplasm morphologically and metabolically may more or less resemble—and apparently endeavour to continue the functional activities of—the normal cells from which they have originated. A sarcoma derived from the mature or immature elements of striped muscle may betray its origin by the striation of some of its cells or fibres, just as an extrahepatic metastasis from a primary carcinoma of liver cells may signify its hepatic glandular descent by the secretion of bile. The presence of bile in some primary hepatic carcinomata seems to have been first described by Perls, in his manual of general pathology in 1877.[2] Analogous observations in regard to other adeno-carcinomata are now too numerous to mention here.[3] No theory regarding benignant or malignant neoplasms can hold good unless it recognizes the above considerations. Apparent exceptions are probably due to insufficient knowledge. Even the various cells of the blood-forming tissues can be the site of neoplastic formation.

But for illustration and confirmation of these points a study of the primary tumours of the endocrine cells of the various endocrine glands is especially interesting. In the short time at my disposal I can do little more than allude to some of them. An important point of distinction between endocrine tumours (that is to say, primary tumours of the endocrine cells of ductless glands) and primary tumours of the secreting cells of the duct glands is that in the former their secretions (as those of the normal endocrine cells from which the tumours arise) are freely absorbed into and distributed by the general circulation.

Before proceeding further I would draw attention to the following points: (1) Although the hormonic effect of an endocrine tumour may, perhaps, be qualitatively not exactly identical with that of the corresponding endocrine gland of a normal individual, nevertheless, on the whole (especially before the tumour cells have become too much altered by malignant change), it may be regarded as the "magnified" hormonic effect (and therefore may even serve to shed light on the normal hormonic functions) of the endocrine gland in question. (2) The hormonic activities of certain endocrine tumours need a youthful body (one still capable of further growth and bodily development) fully to manifest themselves. (3) When one bears in mind that an affection of one endocrine gland must almost necessarily cause reaction in others, it does not seem surprising that the clinical picture in cases of endocrine tumours may sometimes be obscured by pluriglandular symptoms. Macrosomia (precocious bodily growth) or [illegible] syndrome of abnormally large bod[illegible] is to say, precocious sexual and gene[illegible] may be caused by endocrine tumours of the suprarenal cortex, of the anterior lobe of the pituitary gland, of the pineal gland possibly, of the interstitial cells of the testis, and likewise by some ovarian tumours.[4] Active enlargement of the male mamma, as I have elsewhere pointed out, may be excited by, or result from, endocrine tumours or other disturbances of various endocrine organs.[5] (4) Non-endocrine tumours arising in, or in the neighbourhood of, endocrine glands, by pressure, destruction, or stimulation (increased blood supply), may cause endocrine symptoms. (5) Some

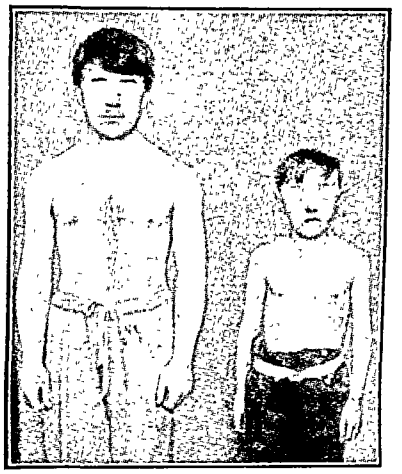
[4] F. Parkes Weber: Loc. cit., p. 20.

[5] For references see F. Parkes Weber, loc. cit., pp. 16, 17.

endocrine tumours may represent an adenomatous form of compensatory (or attempted compensatory) hyperplasia analogous to nodular hyperplasia and adenoma formation in a cirrhotic liver. (6) The signs and symptoms of an endocrine tumour doubtless differ somewhat according to the individual "soil" of the patient (age and potentiality for growth, sex, other constitutional factors), and even according to individual "local soils" of different parts of his body.[6]

Tumours of the Endocrine Cells of the Suprarenal Cortex.—I place these first, because, especially since the well-known publication of Bulloch and Sequeira (1905), they are the endocrine tumours which have probably attracted the most clinical and pathological attention, but further investigation and observation, both pathological and clinical, are needed in regard to them—as, indeed, in regard to all kinds of suprarenal primary tumours. In typical cases their presence can be suspected—before any tumour can be felt—by certain striking symptoms varying with the sex and the age of the affected individual: female virilism or (when the tumour arises in early foetal life) pseudo-hermaphroditism, "precocious" obesity, hypertrichosis (hirsuties), cutaneous "striae," alteration in texture, vascularity, and sometimes in pigmentation of the skin. In adult females the clinical signs may be limited to amenorrhoea or irregular menstruation[7] and possibly adiposity, with cutaneous pigmentation. In a woman, aged 36 years, not only was there facial hairiness with coarseness of skin, but the pilo-sebaceous development progressed to the commencement of seborrhoeic baldness of the ordinary middle-age male type.[8] The blood pressure may be more or less raised, as in primary tumours of the chromaffinic cells (to which I shall allude further on), but this may sometimes have been due to associated arterio-sclerosis or contracted kidneys. In boys there may be "male virilism," with precocious obesity or excessive muscular development.

Dr. Sacchi's patient at the age of 10 years (fifteen days after the operation).



Mr. R. P. Rowland's patient at the age of 9 years, with a normal boy of the same age.

Two points to be remembered are that more or less similar symptoms may be present in the absence of a definite suprarenal cortical tumour, and that the results of operation have been often unsatisfactory, owing to death resulting directly from the operation[9] or to recurrence of the malignant tumour.[10] To what extent deep x-ray and radium treatment can be of use in such cases remains to be seen.

In some cases it is possible that the remaining suprarenal gland, if not actually hypoplastic, is at least functionally insufficient just after the gland containing the endocrine tumour has been removed. What would happen, I wonder, if one of the rare insulin-producing pancreatic tumours, which I shall refer to further on, could be suddenly removed? Surely the patient would become dangerously hyperglycaemic if not at once *treated by insulin injection.*

Tumours of the Chromaffinic Cells of the Suprarenal Medulla.—Some of these rare cases have been clinically characterized by remarkable paroxysmal attacks of high blood pressure, or by signs suggestive of contracted kidneys *together with diabetes mellitus, the high blood pressure* being apparently due to the secretion of adrenaline by the tumour cells.[11]

Endocrine Tumours of the Pituitary Gland.—Besides the eosinophil-cell tumours of the anterior lobe that give rise to acromegaly, it seems that basophil-cell tumours may sometimes exert an endocrine effect—namely, in regard to sexual development. I am indebted to Professor Arthur Ellis for references to papers by Evans and Simpson and others bearing on this subject.[12] In the case of the woman, aged 28 years, with complicated endocrine symptoms, whose case I described in 1926, amongst other post-mortem findings was a minute basophil-cell adenoma in the anterior lobe of the pituitary gland.[13]

Endocrine (Primary Insular) Tumours of the Pancreas.—In my recent paper (1929) on endocrine tumours at the Royal Society of Medicine I gave abstracts of the three first cases (all American) probably of this nature. They were clinically characterized by spontaneous hypoglycaemic attacks.[14]

Endocrine Tumours of the Thyroid Gland.—Von Eiselsberg's classical observation of 1894 should be specially referred to, owing to its important position in the history of the study of endocrine tumours. The patient was a woman, aged 38 years in 1886, *when Billroth excised her* enlarged thyroid gland. The operation was followed by myxoedema. Subsequently a tumour appeared in the upper part of the sternum, and as it increased in size the myxoedema disappeared. In 1892 the sternal tumour, which was then as large as a fist and appeared to be malignant, was removed by von Eiselsberg and was found to contain colloid material, as a thyroid tumour does. The woman recovered from the operation, but the myxoedematous symptoms recurred in the same order as after the original thyroidectomy operation, and they persisted.[15]

Endocrine Tumours of the Testis and the Ovary.—Precocious sexual and general bodily development have long been known to be sometimes associated with a tumour of the testis or the ovary. Probably the most remarkable case of the kind was that published by Ercole Sacchi of Genoa, in 1895. The patient was a boy, aged 9½ years, in whom excision of the large left testis, which contained a carcinoma-like tumour, was gradually followed by disappearance of the signs of precocity; his beard dropped off and mentally he became more childlike.[16]

[7] See the recent case of suprarenal cortical adenoma successfully removed from a woman aged 48 years, recorded by J. B. Hicks, *New England Medical Journal*, Boston, 1928, cxcix, p. 1140.

[8] C. G. Murray and G. S. Simpson: *Lancet*, London, 1927, ii, p. 745, and 1929, i, p. 856. The signs of virilism disappeared after operative removal of the tumour (in November, 1926), and the scalp hair began to grow again. Unfortunately there was soon recurrence of the tumour with return of the cutaneous signs, and death occurred in November, 1928. H. W. Barker, who correctly diagnosed the case in 1926 (chiefly owing to the pilo-sebaceous changes), referred to it in his Lettsomian Lectures of 1929.

[9] See the recent case reported by Langeron, Dechert, and Danes, *Bull. et Mém. de la Soc. Méd. des Hôp. de Paris*, 1929, Series 3, xlv, p. 456. The patient, a woman, aged 20 years, died suddenly forty hours after the operation. There was no post-mortem examination.

[10] Cf. the case of Murray and Simpson, *loc. cit.*

The testicular and ovarian tumours associated with macrogenitosomia have, after microscopical examination, been described under various names, but in Mr. R. P. Rowlands's recent case of macrogenitosomia in a boy, aged 9 years, the tumour which he successfully excised was regarded by Professor Adrian Stokes and Dr. G. W. Nicholson as having arisen from the interstitial cells of the testis.[1]

SOME ACUTE NASAL AND AURAL CONDITIONS SEEN IN GENERAL PRACTICE.*

BY

N. STUART CARRUTHERS, F.R.C.S.Ed., D.L.O.,

SURGEON IN CHARGE OF EAR, NOSE, AND THROAT DEPARTMENT, NORFOLK AND NORWICH HOSPITAL; AURAL SURGEON, JENNY LIND HOSPITAL, NORWICH.

IT is becoming increasingly recognized by the profession that acute nasal sinus infection is much more common than many of us have imagined. Cases of influenza that failed to respond to treatment as quickly as they should, and in which the headache and temperature persisted in a most unaccountable fashion, must be familiar to us all. There is no doubt in my mind that in many of these cases the continuance of the symptoms was due to infection in one or more of the nasal sinuses. I shall cite a case in illustration.

A cook went to bed on February 12th with all the symptoms of severe influenza: headache, backache, a temperature of 104° F., general malaise, slight sore throat, and some cough. In spite of skilled treatment the temperature and headache remained a marked feature until February 26th, when her doctor asked me to see her.

The initial temperature had dropped on the second day of the illness, but since then she had persistently run a temperature of 99° to 102° F. The headache was described as "being all over the head," but I elicited the fact that it was felt more in the front than in the back of the head. Examination revealed a considerable quantity of muco-pus in both nostrils, and slight tenderness in the canine fossa on each side. The antra were dull on transillumination, and a diagnosis of suppuration within them was readily made. The usual conservative treatment of inhalations and sprays was tried for three days, but, the condition not improving, the patient was admitted to hospital and, under a general anaesthetic, both antra were opened and drained intranasally. They contained thick pus from which a streptococcus was cultivated. The patient made an uninterrupted recovery.

In considering the nasal accessory sinuses it is necessary to recall that the ostia of them all are extremely small, and that those of the anterior group of cells—namely, the frontal sinuses, the anterior ethmoid cells, and the maxillary antra—open into the nose beneath the middle turbinate bone. Any infection, therefore, of the nasal mucous membrane which causes engorgement of the middle turbinate bone and of the lips of the ostia may lead to the retention of inflammatory products within the sinuses. Should infection have reached the interior—and there is no doubt that in even the common "cold" it usually does—the result will be an ill-defined headache with more or less temperature, depending on the virulence of the infecting organism and the sinus involved.

THE DIAGNOSIS OF ACUTE SINUSITIS.

Usually the sinuses infected are those of the anterior group, and most commonly the maxillary antra and the frontal sinuses.

Acute Frontal Sinusitis.

The most striking feature of frontal sinus suppuration is the pain, which has a definite periodicity. For some reason not satisfactorily explained it starts about 10 or 11 o'clock in the morning and gets progressively worse until it reaches its height about lunch time, after which it subsides, only to start again the following day at the same time. A pain of this type affecting the region of the frontal sinus is absolutely pathognomonic of infection within the sinus. It never keeps the patient awake at night, and if he complains that he cannot sleep for pain it is certain that the condition has either progressed to an osteomyelitis of the frontal bone, in which case a history of the typical pain would be obtained, or that it is due to some other cause not associated with the frontal sinus.

Tenderness over the sinus is a useful diagnostic sign, but care must be exercised not to press on the supra-orbital and supra-trochlear nerves, which are tender to pressure in all of us. When only one of the frontal sinuses is suspected, it is helpful to exert the same amount of pressure with an index finger over each sinus simultaneously, and ask the patient which is the more tender. It is much more reliable than pressing on the suspected sinus only, pain and tenderness being purely relative. Tenderness over the floor of the sinus—that is, over the area just above the inner canthus—is usually very pronounced, and is, in my experience, a more reliable sign than tenderness over the anterior wall. Discomfort on looking to one or other side is common, and is due to the fact that the pulley of the superior oblique muscle is attached to the periosteum of the floor of the sinus. Temperature is a very variable symptom; it may be absent or it may be as high as 105°. Generally a lower temperature—99° to 102°—is to be expected, but this depends on the virulence of the infecting organism. Oedema of the upper eyelid is not seen until late in the disease, and should not be allowed to develop if the patient is seen in the early stages. Photophobia is not uncommon, but is also usually a late symptom.

It is interesting to note that most of the cases of chronic sinus infection, which are the result of a previous acute infection, give a history of influenza some years previously, accompanied or followed by severe frontal headache which was treated as "neuralgia." In neuralgia, however, the pain is confined to the area supplied by the nerve involved. It has no definite periodicity like the pain of frontal sinusitis; moreover, the nerve itself is actually tender on pressure, whereas in frontal sinus infection it is the bone that is tender.

Another cause of acute frontal headache is acute maxillary antrum suppuration. In this condition the pain is frequently referred to the forehead, but it lacks the periodicity of true frontal sinusitis pain, and, unlike it, often keeps the patient awake at night.

The intranasal signs of frontal suppuration are seldom characteristic, but usually some injection of the affected side can be made out, especially of the middle turbinate bone. Frequently the septum is deflected to the diseased side and, by preventing free drainage, may act as a contributory cause. When pus is seen, it is either under the middle turbinate and farther forward than in the case of antral suppuration, or it is in the olfactory cleft—that is, between the septum and the middle turbinate bone. Often no pus is seen unless the patient is examined towards the evening, after the pain has passed off.

Transillumination as an aid to the diagnosis of acute frontal sinus suppuration is not of great value. The sinuses vary very much in size. In some patients the sinus of one side may be large and the other small or even absent, and it is difficult to be certain whether the failure to illuminate is due to a small sinus or to the retention of inflammatory products within a large one. A radiogram, however, is of the greatest help, and should always be obtained if operation is contemplated; it shows what manner of sinus is being dealt with. The most useful view, in my opinion, is the "nose-chin"—that is, one taken with the patient's nose and chin resting on the plate.

In the surgical treatment of frontal sinus suppuration I would stress the need of doing as little as possible. There is seldom any reason to open the sinus externally; more often than not all that is required is the removal of the anterior end of the middle turbinate bone. We are endeavouring to combat what is generally a virulent infection, and our aim should be to limit it rather than to spread it by opening up fresh bone and other tissues. If the cause of the retention of secretions is a small fronto-nasal duct, and not an enlarged middle turbinate, it can be quite sufficiently enlarged intranasally with a rasp.

[1] By the kind permission of Mr. Rowlands I was able to give illustrations of his case (which had not previously been published) in my paper on Endocrine Tumours, *Proc. Roy. Soc. Med.*, Section of Medicine, 1929, xvii, p. 15.

* A paper read before the Norfolk Branch of the British Medical Association.

Acute Antral Suppuration.

The ostium being situated some distance above the most dependent part of the cavity, drainage of the antrum is inadequate, and stagnation of infected secretions is more likely to take place than in any of the other nasal sinuses. We would therefore expect suppuration within the antrum to be relatively common, as indeed it is.

Most of the acute antral cases that I see are sent to me by dental surgeons. The history is nearly always the same: the patient has had a "cold" or an attack of influenza associated with pain in the cheek, which he attributes to defective teeth and which the doctor has advised he should have extracted. Sometimes the dental surgeon has reported that there are no teeth likely to be the cause of the pain, but more often he has extracted one or more teeth, and when relief has not been forthcoming has passed the patient on to me. I am sure that if we keep the possibility of antral infection in our minds, we shall be less frequently "caught out." As in the case of many other diseases, we have only to realize its relative frequency to be on the look out for it and diagnose it when we see it.

The symptoms are generally as follows: The patient has a "cold" associated with nasal obstruction and discharge, slight malaise, ill-defined headache, and a rise of a few degrees in temperature. A feeling of distension, or pressure, in one or both maxillae is practically always present, and is due at the beginning of the illness more to swelling and hyperaemia of the maxillary mucosa than to the internal pressure of pent-up secretion. As the disease progresses, the feeling of distension, which is increased by the act of stooping or coughing, is replaced by neuralgic pain commonly referred to the teeth of the upper jaw, but frequently to the supra-orbital region of the same side. Killian goes so far as to say "the site of predilection is the supra-orbital area." My experience does not wholly confirm his view, but pain in this site is very common, and many frontal sinuses have been opened needlessly through overlooking this fact. Sometimes there is no actual pain in the upper jaw, but an uncomfortable sensation as if one tooth was loose, or longer than its fellows.

If the maxillary ostium is completely occluded and the infection a virulent one, swelling of the cheek with oedema of the lower eyelid is observed, and great tenderness accompanies pressure on the facial wall of the sinus. In these circumstances absence of nasal discharge is common, but congestion and obstruction in the corresponding nostril is always present, and the sense of smell is either diminished or lost.

On examination one finds an intensely injected nasal mucosa and enlarged turbinates; muco-pus may be seen issuing from beneath the middle turbinate bone, but this may not be possible until the mucous membrane has been constricted with adrenaline or cocaine. The postural test, which consists of inclination of the head forwards and downwards, so that the ostium is the most dependent part of the sinus, may help, but this test is more useful in chronic cases.

Pressure over the anterior wall of the canine fossa will always produce discomfort, and it is most important to compare the two sides by pressing on them simultaneously. Transillumination is of great value and should be practised whenever antral suppuration is suspected; it can be done quite well with one of the small "fountain pen" flash lamps which many of us now carry. Darken the room as far as possible, and make a tent to cover the patient's head and your own; insert the lamp in the mouth, taking care that the upper denture, if present, is removed. The normal light area immediately below the orbit will be absent if the antrum is infected. A good radiogram is useful to confirm the diagnosis, and when the pain is referred to the supra-orbital area it is an essential to exclude frontal sinus suppuration.

Acute Ethmoiditis.

Acute infection within the anterior ethmoid cells is probably very common, but is seldom diagnosed unless complications arise. It is difficult to enumerate the precise symptomatology, for the reason that the condition is seldom met with alone, but in association with infection of some of the other nasal sinuses, or as a complication of acute coryza. Headache is a constant symptom, and is referred to the region between or behind the eyes, and is aggravated by movement of the eyeball. Tenderness can often be elicited by digital pressure below the inner canthus. (In frontal sinus suppuration the tenderness is above the canthus.) Radiography is valuable, but as the condition usually clears up without undue delay, it is seldom called for.

Acute Sphenoidal Suppuration.

Acute sphenoidal suppuration is a condition of considerable interest to the rhinologist, if not to the general practitioner, for it is a very definite entity and by no means rare, although little or nothing is said about it in any of the textbooks. Briefly, the symptoms are headache and raised temperature. The headache is of a particularly distressing kind, and is deep-seated and intense. Usually it is referred to the occiput, but sometimes to the parietal or temporal region. The patient gets no rest from it, either by night or day, and often screams out unless a sedative is given. The condition is sometimes mistaken for meningitis, and in many cases, unless appropriately treated, it undoubtedly progresses to meningitis. A physical sign that is not easily explained is proptosis of the upper eyelid on the affected side.

TREATMENT OF ACUTE SINUSITIS.

It is a mistake to imagine that most of these cases require surgical intervention; if properly treated in the first place, very few of them will.

Confinement to bed, or at least to a warm room, is most desirable. A dose of calomel should be given, and, the essence of the treatment being to reduce the engorgement of the mucous membrane, smoking and the consumption of alcohol, which increase it, should be forbidden. Heat, either in the form of fomentations or as radiant heat, is most comforting, especially in frontal sinusitis.

Intranasally, inhalations of steam impregnated with menthol are useful, especially when given in the form of an alcoholic solution. Half a teaspoonful, or a little more, of a 15 per cent. solution should be put in a quart jug, the water being at a temperature of 140° to 150° F., and the inhalation continued for ten minutes and repeated every four or five hours. A nasal douche should not be used during the early stages; the patient should be encouraged to blow his nose, though he must take care not to do it so violently as to cause the infection to spread up the Eustachian tube to the middle ear. There is no objection to a warm alkaline spray used in a coarse atomizer, and it is comforting to the patient. Aspirin, phenazone, bromide, and Dover's powder are all useful in relieving the pain.

If in spite of this treatment the symptoms persist for two or three days, it is probable that some slight surgical intervention is necessary. The failure may be due to a deflected septum or an enlarged anterior end of the middle turbinate, which will have to be removed under a general anaesthetic. The earlier diagnosis of sinus suppuration has greatly simplified the operative treatment, and it is now seldom necessary to resort to the mutilating operations of a generation ago. There is no reason to open an antrum through the buccal cavity, or the frontal sinus externally; they can both be satisfactorily dealt with by intranasal surgery.

ACUTE AURAL CONDITIONS.

The only common acute aural conditions I propose to discuss are acute middle-ear suppuration and acute mastoid disease. I operated on a great many acute mastoids during the recent epidemic of influenza, and what struck me most was the fact that whereas a few years ago it was common to see the old textbook picture of the auricle pushed downwards and forwards, I saw only three or four cases presenting this symptom. The earlier diagnosis of acute mastoiditis, which is often by no means easy, reflects the greatest credit on the care and vigilance of the general practitioner.

Acute Otitis Media.

Acute otitis media is generally an ascending infection, characterized by a sense of fullness going on to actual and very acute pain in the ear. The pain is worse at night and may render sleep impossible. Warm olive oil or, better still, glycerinum acidi carbolici (5 per cent.) may relieve it; if not, I cannot too strongly stress the necessity for an early paracentesis. Many cases of mastoiditis are the result of delay in carrying out this operation, and I am quite certain that we are never justified in waiting for days, as we used to, until the drumhead gives way. After all, paracentesis is a very simple procedure. Anyone, given a good light, an aural speculum, and a myringotome, can do it while the patient is under gas or ethyl chloride. The relief from pain is often instantaneous, the risk of mastoiditis reduced at least by half, and the hearing is less likely to be impaired than if the drum were allowed to rupture on its own. It is better to open a drum unnecessarily than to let the case drift on to mastoiditis.

Assuming the patient has had paracentesis performed, or that the drum has given way, and the ear is discharging freely, how are we to know that all is going well and that the mastoid is not becoming infected? A decision is not always made easily, and there is no one infallible symptom to look for, though mastoid tenderness is significant. Unfortunately some mastoid tenderness is usually present in otitis media. The mastoid antrum being a direct backward extension of the middle ear, pus practically always finds its way into it; but that does not constitute mastoiditis, though it explains why patients with marked mastoid tenderness frequently get completely well in a few days. The tenderness associated with suppuration in the mastoid antrum, as distinct from the tenderness of mastoiditis, is situated over Macewen's triangle—that is, the area above and behind the meatus, and not at the tip of the mastoid process. If, then, it is found that the area of tenderness is extending towards the tip, and the patient's constitutional symptoms are becoming worse, it is safe to assume that the case is going on to mastoiditis. It should be remembered that it is rare for an adult patient to have a temperature of over 100° F. in mastoiditis, and a high temperature is not to be waited for, as it usually means some intracranial complication.

In testing for tenderness it is most important to compare the two sides, and, in a case of suspected suppuration within both mastoids, to compare one mastoid at a time with any other part of the skull. This is done by exerting equal pressure with the index fingers, and, by varying the degree of pressure, it is possible to get a very fair estimate of the degree of tenderness. In carrying out the test do not ask, "Does that hurt?" Rather say, "That does not hurt, does it?" and unless the tenderness is real the patient will agree with you. It is also helpful to watch the patient's face while carrying out the test, as you will often see an uncontrollable frown when you press on a tender area. Pain is a very helpful sign. The pain of otitis media usually passes off soon after the discharge is established. If it persists and robs the patient of a night's rest in spite of free discharge, he is probably developing mastoiditis. The arrest, or diminution, of the discharge followed by increased tenderness is another significant sign, and should suggest the possibility of spreading infection.

Briefly, then, the return of pain in spite of a free discharge, extension of tenderness towards the tip of the mastoid process, and increase in temperature and malaise, may be taken as indications that mastoid infection is taking place. The usual symptoms and physical signs may vary slightly according to the age of the patient.

Mastoid Abscess.

One sometimes meets with a mastoid abscess in a child under 12 months old. Generally the first sign noticed is a swelling behind the ear. The child may have been fretful for some days and its condition attributed to teething. The discharge from the ear is probably ascribed to the same cause, and it may not be until the swelling appears that the mother seeks advice. The constitutional symptoms are usually slight, and I have seen cases where the house-surgeon has incised the swelling, in the belief that it was merely a post-auricular abscess secondary to a breaking down gland. I always tell my house-surgeons that post-auricular abscesses in children, with or without discharging ears, are mastoid abscesses and the result of extensive bone disease. That may not be strictly correct, but I have yet to see the case in which it is not.

Mastoid suppuration in the aged also presents certain difficulties. Oedema is practically never seen, as the bone is too sclerosed, and tenderness has to be carefully looked for to be found; very often it is confined to one small area. The patient will complain of deep-seated boring pain that robs him of sleep, and, as often as not, the only other evidence of ear trouble will be a profuse discharge from the meatus. The temperature will not be more than 99° or 100° F. at most. The amount of discharge is usually suggestive. The cavity of the middle ear is small and the secreting powers of the lining membrane accordingly are limited; if, then, the discharge is copious, it must be coming from somewhere else, and most likely from a diseased mastoid bone.

In the last few months I have seen several cases of mastoid abscess in which the drum was intact and normal. They were interesting because, otorrhoea being absent, mastoid disease was not suspected. They all gave a history of having had severe earache, which had improved but never completely disappeared. The explanation was evidently that the Eustachian tube was fairly patent and the drum tough. The middle ear and mastoid antrum had emptied themselves through the Eustachian tube, but some residual infection had persisted in the mastoid bone and gone on to abscess formation. Most of the patients were elderly adults, and one of them gave a six months' history, during which she had been labelled "neurotic." She had marked mastoid tenderness and at the time of operation a large perisinous abscess was found. The absence of discharge coupled with the normal drumhead entirely misled her doctor. In this connexion it is useful to remember that there are many causes of mastoid pain not associated with ear disease, but there are very few causes of mastoid tenderness other than the existence of disease within the mastoid bone.

TREATMENT OF MASTOIDITIS.

The classical operation is, of course, the Schwartze, and the ultimate results leave nothing to be desired. Until a few years ago the custom was to leave the wound open and to pack the cavity with gauze. This meant a daily—and painful—dressing for the patients, and the discomfort was often such that they remembered it to the end of their days. Just after the war the practice of rubbing bipp into the cavity and completely suturing it, was tried with more or less success. Unfortunately, although it robbed the operation of the terror of a very painful dressing, quite half of the wounds completely broke down.

A modification, and the method at present generally used, is lightly to pack the cavity with gauze, stitch up the upper two-thirds of the wound and leave it for four or five days. The packing can then be removed without causing much discomfort, but the patient may find its presence distinctly painful. To overcome this disadvantage I have used a piece of rubber tissue in place of gauze. It slips out painlessly and the results have been very satisfactory. Recently one of my hospital sisters noticed that, with the rubber tissue as a packing, one had frequently, on the third or fourth day, to take out one or two of the stitches at the upper part of the wound owing to pus having collected under them. She suggested that this could be prevented by stitching up the wound completely and securely, and passing a small rubber tube with lateral holes, from the extreme upper end of the wound through the cavity and out at the lower end. The tube should be made of rather rigid rubber to prevent its collapsing, and have a total calibre of not more than that of a slate pencil. It is left in for three or four days, during which the mastoid cavity is syringed daily through it from above downwards, and if the discharge is free, the tube is retained a day or two longer.

The cases treated in this manner have, without exception, done remarkably well. In none of them has the wound broken down, and in all of them the convalescence has been considerably shortened. Frequently the wound is soundly healed, all discharge has ceased, and the patient is out of hospital on the tenth or eleventh day. Compared with the old laborious daily packing, which often had to be done for anything up to two months, it is an advance of the greatest importance.

INOPERABLE CARCINOMA OF CERVIX TREATED BY RADIUM TRANSPERITONEALLY.

A REPORT OF THREE CASES.

BY

N. ASHERSON, M.A., M.B., B.S., F.R.C.S.ENG.,

LATELY HARKER SMITH RADIUM REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

THE following record of three cases of carcinoma of the cervix treated by radium intravaginally and transperitoneally is based on the notes published in the annual Harker Smith radium report of University College Hospital, and for permission to use this report I am indebted to the hospital Radium Committee. The patients concerned were all under the care of Sir George Blacker, who operated in each case.

CASE I.

The patient, A. B., aged 49, was admitted on April 21st, 1925, with a moderately advanced cervical carcinoma infiltrating the anterior vaginal wall. Microscopical examination showed the growth to be squamous carcinoma.

On April 24th the abdomen was opened, and four tubes, each containing 10 mg. of radium sulphate, screened by 0.3 mm. of platinum, were embedded in the left utero-sacral fold, in the base of the left broad ligament, higher up and further out in the left broad ligament, and in the base of the right broad ligament respectively. Each tube was tethered by phosphor-bronze wire, the distal ends of the four wires being brought out of the wound through a rubber drainage tube. At the end of ten hours the four needles were extracted by traction on the wires, the drainage tube was removed, and the hole closed by tying a through-and-through suture which had been placed in position at the time of the operation.

On May 6th, the wound having healed by primary union, and the patient having made a good recovery from the effects of the operation, 100 mg. of radium sulphate were inserted in the cervical canal, and 100 mg. placed transversely across the vaginal vault, each being screened by 0.5 mm. of platinum and 2 mm. of rubber. The radium salt was left *in situ* for twenty hours, making a total application of 2,800 milligram hours of element.*

On July 10th the patient was readmitted to hospital; she had been well, gained 4 lb. in weight, and had a good appetite. There was no bleeding, but a slight yellowish discharge. Her bowels were regular. The cervix had been replaced by a depressed area about the size of a sixpenny-piece, consisting of red granular tissue which bled on examination. Radium treatment was administered as follows: one tube containing 50 mg. of radium sulphate, screened with 0.5 mm. of platinum and 2 mm. of rubber, was placed into the cervical canal; one tube containing 100 mg. of radium sulphate, similarly screened, was placed transversely across the vaginal vault. The tubes were kept *in situ* for twenty-four hours, involving the application of 2,520 milligram hours of element.

On September 22nd the patient was once more admitted to hospital; she was very well, had a good appetite, had increased in weight, there was no bleeding, and very little discharge. Hot flushes were troublesome. On examination the vagina was found to be shortened and its upper part conical. The vaginal cervix had disappeared and the uterus was fairly mobile; both utero-sacral ligaments were palpable but not thickened or shortened. The abdominal scar was sound; there was no evidence of growth on inspection or palpation.

In November, 1927, the patient complained of pain in the leg and arm; *x*-ray examination showed the presence of osteo-arthritis. No evidence of growth was found on vaginal examination; on rectal examination both utero-sacral ligaments were found to be indurated, though no definite mass was palpable. The mucous membrane of the rectum felt normal, and the fact that the patient was passing clots of blood with her motions was attributed to the possible presence of a radium burn of the rectum.

In May, 1928, nothing abnormal was found on abdominal examination, but the vagina was occluded by adhesive vaginitis. The utero-sacral folds were slightly thickened, but there was no clinical evidence of growth. In March, 1929—nearly four years after the beginning of treatment—the patient was alive and well.

CASE II.

The patient, A. C., aged 52, was admitted on September 7th, 1925, complaining that for four months she had had a watery, and occasionally blood-stained, discharge from the vagina. She had no pain and the bowel and bladder functions were normal. She had had three children (no miscarriages), the last pregnancy having occurred eleven years and the menopause two years before the onset of symptoms. On examination the cervix was found to be enlarged and torn on the left side; posteriorly it was partially destroyed by a friable growth which bled readily. The vagina was not actually invaded, but the cellular tissue on the left side was somewhat thickened and the uterus slightly fixed. Microscopical examination showed the growth to be a squamous carcinoma.

On September 11th, and again on September 14th, acetone was applied for ten minutes, and an operation was performed on September 16th. The original intention was to carry out Wertheim's extended hysterectomy, but this idea was abandoned when it was found that the growth had invaded the peritoneum from the right posterior part of the cervix, causing partial obliteration of the pouch of Douglas, and was just beginning to invade the rectum. Furthermore, the uterus was tethered on the right side by a definite invasion of the broad ligament. The ovarian vessels and round ligaments were tied and, by a technique similar to that used in Case i, five tubes, each of 10 mg. of radium sulphate, screened by 0.3 mm. of platinum, were embedded as follows: one tube in the near end of the base of the right broad ligament; one tube further out between the right broad and utero-sacral ligaments; one tube in the mid-line of the cervix just below the internal os; one tube behind the cervix, half an inch to the left of the mid-line; one tube in the base of the left broad ligament. The tubes were allowed to remain in position for ten hours, the total dose being 350 milligram hours of element. After the operation the patient had an uneventful convalescence, and on October 2nd, and again on October 6th, acetone was applied.

On October 9th radium treatment was resumed. A tube containing 100 mg. of radium sulphate, screened with 0.5 mm. of platinum and 2 mm. of rubber, was placed in the cervical canal, and one containing 50 mg. of radium sulphate, similarly screened, in the right posterior fornix. Both tubes were retained for thirty hours, giving a total dose of 3,150 milligram hours of element.

On June 9th, 1926, there was an extensive papillary recurrence projecting from the cervix; the mass was breaking down, was friable, and it bled on manipulation. The lateral fornices were not involved; the left utero-sacral ligament was normal; but there was marked thickening in the right utero-sacral ligament. An application of 3,100 milligram hours of element was made per vaginam. On July 13th the cervix was largely atrophied and no cervical growth could be detected. The posterior fornix was obliterated, the cellular tissue on the left side was normal, but there was a definite mass in the right utero-sacral ligament.

On November 14th the only abnormal physical sign revealed by abdominal examination was an enlarged and readily palpable right kidney. The cervix was atrophied and flush with the vaginal vault, and there was induration in the right fornix. Rectal examination revealed a large, hard, fixed mass on the right side of the pelvic wall; it was not attached to the rectal mucous membrane. Both utero-sacral ligaments, especially the right, were infiltrated and fixed to the pelvic wall. On November 18th similar conditions were found, and in December, 1928, three years after the beginning of treatment, the patient died.

CASE III.

The patient, F. O., aged 53, was admitted on October 28th, 1925. Examination revealed an ulcer with a thick everted edge and a friable surface, which bled readily on manipulation, replacing the cervix. The uterus was fairly mobile. The left broad and utero-sacral ligaments were to some extent invaded, not the right. There was early extension to the vagina.

On October 30th a tube of radium sulphate, screened with 0.5 mm. of platinum and 2 mm. of rubber, was inserted into the cervical canal, and one of radium sulphate, similarly screened, into the posterior fornix. The tubes were retained for twenty-four hours, giving a total dose of 2,520 milligram hours of element.

On November 13th the abdomen was opened, but the conditions were found unsuitable for treatment by Wertheim's operation. With a technique similar to that used in Case i, five tubes, each of 10 mg. of radium sulphate, screened by 0.3 mm. of platinum, were embedded as follows: three tubes behind the cervix, one median, and one at the extreme lateral margin of each side, a tube in the left utero-sacral fold 1½ inches from the

* To convert radium sulphate to element it is necessary to multiply by the coefficient 0.7.

cervix, and another 1 inch from the cervix. All five tubes were removed at the end of ten hours, making a total application of 350 milligram hours of element.

A section taken for examination was of interest, for though in many places it showed ordinary squamous carcinoma, in several areas the cervical glands were normal, and columnar epithelium of some of these appeared to merge into the squamous growth. The suggested explanation was that trabeculae of the squamous carcinoma had tended to grow down the cervical glands and gradually to replace the normal epithelium; such trabeculae had in consequence obtained a central lumen.

After the operation the patient's progress was uneventful. On February 2nd, 1926, examination showed that the upper end of the vagina was scarred and the cervix somewhat enlarged; the mucosa was intact. There was a diffuse thickening of the cellular tissue on the left side of the pelvis, due either to the presence of growth or to fibrosis. An application of 1,256 milligram hours of radium sulphate was made per vaginam. On August 24th, 1926, examination showed the presence of a hard fixed mass in the pouch of Douglas; the patient was given lead treatment at the Cancer Hospital, but she died shortly after, having survived fifteen months since the beginning of treatment.

SUMMARY.

Case i was alive and clinically free from disease four years after treatment; Case ii died three years, and Case iii fifteen months, after treatment. Curiously enough, the disease in Case i was more advanced than in the other two. For purposes of comparison I may mention that at University College Hospital during the past six years 14 patients with operable cervical carcinoma were treated by radium alone, and of these 7 are dead; 7 patients are alive, 1 five and a half, 1 four and a half, 1 four, and 4 three and a half years after the first radium treatment. The average period of survival among the patients who died was twenty months.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF GLANDULAR FEVER.

THE following clinical details of a case diagnosed eventually as glandular fever seem to be worth recording.

A married woman, aged 48, on January 1st, noticed vague pains about the neck; this fact was not mentioned until later. During the night of January 2nd she had most violent pains over the base of the right lung, and general abdominal pain. There was no sickness, the bowels were not open, and there was no abdominal rigidity; the temperature was 100° and the pulse rate 105. The breath sounds at the right base were diminished, but there was no cough. The next day her condition was much about the same, the temperature and pulse being unchanged.

On January 4th pains in the neck developed and the glands of the right side of the neck became slightly enlarged. The temperature was 100.8° and the pulse 106, morning and evening. On the next day the glands on both sides of the neck were tender and enlarged; the temperature had risen to 101° and the pulse to 110, morning and evening. During the next twenty-four hours the glands of the neck became rather smaller and slightly less tender; the temperature was 100.6° and the pulse 100.

On January 7th the glands in the neck were decreasing in size, but she complained of pains in the sternum and slight tenderness in the axilla; the glands in the groin were tender and a little enlarged. The temperature was 98.6° and pulse 100. The breath sounds at the right base still remained rather weaker than at the left. By the next day the glands in the groin were tender and enlarged; there were pains in the lumbar region, tender and slightly enlarged axillary glands, and tenderness of the epitrochlear glands. The pain over the sternum was better. The temperature was 99° and the pulse 88. On January 9th there was still slight tenderness of the glands in the groins, neck, axilla, popliteal glands, and the epitrochlear glands; the temperature was 99° and the pulse 78. There was slight cough, but the heart and lungs appeared normal, and the general condition was improving. On the following day she developed a cold, and there were signs of bronchitis. The axillary and epitrochlear glands were still tender and slightly enlarged, and there were pains in the lumbar region; the temperature was 99.4° and the pulse 88. During the next twenty-four hours the axillary glands remained tender, and there were still signs of bronchitis. The temperature was 99.2° and the pulse 80.

On January 12th she was practically clear of any pain or tenderness, but still complained of the "cold." The temperature was 98.2° and the pulse 74. Two days later the chest was clear and the "cold" better, but she still complained of vague pains in the axilla and groins. The temperature was 98.4° and the pulse 74. She was allowed to get up for a short period. On January 16th the patient felt very much better except for general weakness. The temperature was 98° and the pulse 80. She eventually made a complete recovery, although convalescence was rather prolonged.

The case was of interest in the early stages when the diagnosis of pneumonia seemed possible, although the absence of cough was against it. Later the existence of some abdominal condition was suggested. The signs in the chest in the early stage were probably due to the enlargement and pressure of bronchial glands, and the abdominal pains would suggest that the mesenteric and retroperitoneal glands were also involved.

This was the first case I had seen, and, so far as I know, no other case had occurred in Leicestershire at that time. During this period and afterwards I was unable to discover any mild case that might be mistaken for the condition, and possibly go unrecognized.

Coalville, Leicester. A. M. W. SEGERDAL.

DIABETIC GANGRENE OF FACE.

THIS case of diabetes, in which gangrene developed in an unusual site, was considered of sufficient interest to make a brief note accompanying a photograph.

The condition was resistant to treatment, and ran a fatal course of seven days, mercifully without severe pain. At the time of onset the patient was receiving insulin and dietetic treatment on usual lines. The first thing noted was a hyperaemic area immediately under the right orbit, which spread, similarly to erysipelas, from that centre; the eyelids swelled up and occluded the eye, which became proptosed with orbital cellulitis. The other eye became similarly affected, while the skin changed to patchy, moist, black sloughs. A photograph, unfortunately, does not clearly show necrosed tissue. Coincident with the local condition, sugar and acetone reappeared in the urine.

I am indebted to Dr. Aveling, physician in charge of the case, for permission to publish this note, and to Miss Houghton, sister in the *x*-ray department, for the photograph.

G. PRATT BROOKS, M.R.C.S., L.R.C.P.,
Acting Resident Medical Officer, Watford and District Peace Memorial Hospital.

TREATMENT OF FILARIASIS BANCROFTI.

WITH the hope that this communication will be seen by practitioners living in places where cases of filariasis bancrofti occur, I am sending you some notes about a patient treated here recently with weekly injections of moogrol in 1 c.cm. doses.

A man, aged 40, had been known to me for years as a healthy, hardworking washerman. He came to my dispensary one morning and showed me a much enlarged leg, which he said he had had for two months. In his night blood I found numerous *Filaria bancrofti*, and the question then came up how to treat him. I was aware that my friends had given novarsenobenzol and numerous other drugs with only partial relief, so decided not to try any of these.

So far as I knew, no patients had been given moogrol or other drugs of the chaulmoogra group, so I decided to try it. At the end of the first week the man returned and said that he felt better; the leg did not look so tense. He has now had six injections; he is able to get back to work, and he walks much better. Measurements show that the calf is losing between one-half and one-quarter of an inch in circumference per week. The blood has not been examined again.

We see very few fresh cases of this condition here, but, for the most part, old chronic cases in which little hope can be given.

My great wish is that others may try this treatment in places where there are a greater number of cases than we have here.

Swatow, China. C. H. BRANGWIN.

Reviews.

OSTEOMYELITIS AND COMPOUND FRACTURES.

THE treatment of acute osteomyelitis was discussed at length at a meeting of the Orthopaedic Section of the Royal Society of Medicine early in 1928, and we reviewed that discussion in a leading article on March 17th. But no allusion to the method of treating the disease advocated by Dr. H. WINNETT ORR of Nebraska was made in that discussion or in that article, and it is doubtful whether Dr. Orr's papers contributed to periodicals in America had then attracted any notice in this country. He has now published an account of his method as applied not only to osteomyelitis, but also to compound fractures, with a discussion of the treatment of suppurating wounds and compound fractures in the late war, and a criticism of the treatment pursued in such cases in America in recent years. His book[1] contains clinical histories of numerous cases treated by himself and others, and its appearance challenges study and comment, and, in view of the results recorded, should lead surgeons to reconsider their methods of treatment, for if Dr. Orr and his disciples are in the right, considerable changes in post-operative technique are called for. It is indeed somewhat startling to read of case after case of acute as well as chronic osteomyelitis operated upon by free incision, removal of sequestra, and "saucerization" of the cavity, then packed and covered with vaseline gauze, and not dressed for several weeks, to be found healed and the gauze pad extruded on the occasion of the first dressing.

Like all other competent surgeons, Dr. Orr insists on the paramount importance of early diagnosis in osteomyelitis and prompt operative treatment. Shortly stated, his principles are the following:

> "First, immediate adequate drainage at whatever stage the osteomyelitis is encountered; second, the maintenance at rest of inflamed parts by the application of a plaster-of-Paris cast, aided, if necessary, by ice-tongs or other methods of skeletal fixation; third, wide open drainage by means of a sterile vaseline pack; fourth, primary asepsis or antisepsis, avoiding the use of irritating antiseptics in the wound; fifth, post-operative care, emphasizing rest without *antiseptic dressings*, which usually increase and complicate infection; and sixth, the maintenance of all injured parts, bones, and soft parts in their correct anatomic position during the entire period of healing."

By "antiseptic dressings" (italicized by the author) is meant, as the context shows, change of dressings as in the daily toilet of an open wound. Dr. Orr has based these principles, he says, on Hunter, Hilton, and Lister. The healing of Lister's first case of treatment of compound fracture under a scab of carbolic acid and blood clot is, he thinks, analogous to healing under the vaseline pad. Septic bones and soft parts cannot be made aseptic with chemicals, the frequent renewal of which leads, like movement of parts, to light up old or add fresh infection. Dr. Orr is a skilful and experienced orthopaedic surgeon, and there is no doubt that with his technique he is able, by intrinsic fixation and extension within a plaster-of-Paris cast, to fix the parts almost absolutely. The method of dry and infrequent dressings was advocated and practised many years ago by Sampson Gamgee of Birmingham and by F. Esmarch of Kiel, but probably neither of those pioneer surgeons would have dared to seal up a bone cavity containing septic material as Dr. Orr does. The proof of the pudding must be in the eating.

The second part of the book is devoted to the study of the treatment of compound fractures on similar principles to those outlined above, excluding, of course, the free exposure and excision of bone. Dr. Orr complains that general surgeons in war and in peace time are apt to pay too much attention to the wound and to neglect the fracture. He relies more upon plaster-of-Paris for fixation than upon splints, although he appreciates the value of Thomas's splints. His methods are well described in this book. It appears that there is one drawback to the Orr method, and that is the putrefaction of the discharge in the vaseline-gauze dressing, a discharge which sometimes oozes out of the end of the plaster cast. Such an "odor" (or, as we would say, a stench) is likely to be very disquieting to the surgeon accustomed to modern surgical dressings, and particularly annoying to the patient and his friends, but Dr. Orr does not allow himself to be disturbed by it, and prefers not to change the dressing, however putrid it may seem, as long as the temperature chart remains satisfactory.

[1] *Osteomyelitis and Compound Fractures and other Infected Wounds.* By H. Winnett Orr, M.D., F.A.C.S. London: H. Kimpton. 1929. (6 × 9¼, pp. 268; 54 figures. 21s. net.)

MATERNAL MORTALITY AND A NATIONAL MATERNITY SERVICE.

IN view of the British Medical Association's memorandum outlining a national maternity service scheme for England and Wales, published as an appendix to the Supplementary Report of the Council in our *Supplement* of June 29th (p. 258), a recent work on *The Causes and Prevention of Maternal Mortality*,[2] by Dr. HENRY JELLETT, is worthy of study and consideration at the present time, when this subject is so much under discussion.

Dr. Jellett is always fearless, and holds decided views, but he has sound foundations on which to carry them in his wide obstetric experience as a former Master of the Rotunda and teacher in the Dublin School, and afterwards as consulting obstetrician to the Department of Health in the New Zealand Government. Except that he makes more of the place occupied by the maternity nurse who is not a midwife, his ideal service, as outlined in this book, follows closely on the lines of the memorandum, though he puts the case in a different, but very characteristic, way. He argues that 85 per cent. of women would pass through pregnancy and deliver themselves safely with the assistance of a midwife only, and for those 85 medical assistance would but increase the danger of infection. The remaining 15 per cent. would suffer materially from the absence of medical aid, and possibly 5 of these 15 might die from the lack of it. Though impossible to group patients into those for whom medical aid is unnecessary, advisable, or essential, he concludes that if the women have adequate preliminary medical examination, and those adjudged normal are left to the midwife with a general practitioner on call in case of need, and an obstetric specialist on call at the request of the practitioner, the basis for an ideal midwifery service is obtained. The argument for a midwifery service of this nature is strengthened by statistics from this country and from other countries with a service of well-trained midwives. The Dutch maternity work is explained in full detail and with approbation.

In discussing the causes and prevention of maternal mortality, a variant on the commoner "extrinsic" and "intrinsic" causes is introduced by the use of the terms "personal" and "impersonal," which require much explanation and illustration to make the author's meaning clear. They are intended to convey an entirely different impression from that of the older terms, in that a "personal" cause is one that might be prevented by human endeavour, whereas the "impersonal" causes are not, and therefore, with progress in medicine in general and obstetrics in particular, many of the "impersonal" causes will in time become "personal." Dr. Jellett includes under impersonal causes those in which the circumstances of the patient during her pregnancy or labour are such as to make it, "humanly speaking," impossible to obtain adequate assistance for her, or to avoid infection. In this way he raises an interesting discussion, since these "impersonal" causes are extended even to the length of including bad training of the practitioner by those responsible for his early education. He does not, however, attempt to show how the "personal" factor, in making inadequate use of opportunities during training, is excluded.

Dr. Jellett's work is full of interesting points, often put forward in a brusque, but always striking, way, and will fulfil a useful purpose. The text of his sermon may be found in his introductory chapter. It reads: "We create hospitals which make interference with normal labour easy, and we neglect the essentials which make interference safe, and the teaching which makes it unnecessary."

[2] *The Causes and Prevention of Maternal Mortality.* By Henry Jellett, M.D.Dublin Univ., F.R.C.P.I. Churchill's Empire Series. London: J. and A. Churchill. 1929. (Demy 8vo, pp. vii + 300. 15s.).

ELECTRO-THERAPEUTIC TECHNIQUE.

ACCORDING to the emphatic statements made in the preface, Dr. F. B. GRANGER's book entitled *Physical Therapeutic Technic*[3] is intended "for the physician who has installed a limited equipment" and "has not been written for the specialist in physical therapy." The author therefore deals in his opening chapter with electro-physics briefly and in a non-technical manner; it is a pity, however, that his chapter on the physiological effects produced by electricity, which immediately follows, is reduced to less than two pages. If the general practitioner proposes to install in his consulting room apparatus for, say, ionization, medical diathermy, and ultra-violet light, he wants accurate and full instruction on the type of physiological response these currents will produce. Then, when a case is under review, he can advise the use of these physical means of treatment, confident in the knowledge that the normal physiological reaction to their application will be of the kind to help his patient.

The tendency of recent books on electro-therapeutics to reproduce manufacturers' blocks of apparatus leads to the inclusion of figures that fail to fulfil the true purpose of an illustration. For instance, on page 45, a "galvano-faradic plate" instrument is shown in such a position that little besides the stand of the machine can be seen. On the next page is the exact opposite of this type of illustration; here is an excellent photographic reproduction of the testing electrode Dr. Granger recommends, from which every detail can be seen. Again, on page 107 and page 108 are three beautiful illustrations of the method of preparing "a safety-pin connector," the steps of making this simple and ingenious contrivance being so clearly set out that any practitioner could immediately make this small adjunct to treatment. When, however, we turn to the illustrations of technique in diathermy there is an unnecessary amount of the assistant and patient and apparatus shown; while the detail of the method of application, which should be the essential feature, occupies in consequence so small a portion of the picture that an otherwise valuable illustration becomes of little help.

In the index of diseases practically no mention whatever is made of any original worker in Europe; for instance, Dr. Axel Reyn's and Sir Henry Gauvain's advances on the pioneer work of Finsen in the treatment of lupus and tuberculosis find no mention, and the equally important original work of Drs. Cumberbatch and Robinson in this country on the effects of diathermy in gonococcal conditions is dismissed as follows: "Corbus, of Chicago, has reported good results with the use of diathermy in this condition. At most clinics, however, the results have not been as satisfactory." There is one feature, however, of particular merit in this book, which has evidently been carefully revised for this purpose, and that is that the author is careful to recommend small currents and to warn the reader as to the contra-indications to further treatment.

Taken as a whole the book will give to the general practitioner the personal recommendations and experience of a doctor who has had more than a quarter of a century's practice in his subject. It is a pity that it has two common but unpleasant features of books printed in America: first, it is extremely heavy for its size, and secondly, a steady but continuous unpleasant aroma comes from the open page (not the cover). These perhaps are small points, but none the less important.

THE SUPRARENAL GLANDS.

A VALUABLE but rather dogmatic account of the suprarenal glands and chromaffin organs[4] constitutes the third volume of the treatise on endocrinology by Professors M. LUCIEN and J. PARISOT and Dr. G. RICHARD, all present or past members of the Nancy School of Medicine.

The authors have produced a large volume; moreover, it is very well turned out as regards print, paper, and illustrations, and its price—in welcome and striking contrast to the prices charged for German medical works of a comparable nature—is very moderate, being only 100 francs. Within its scope the work includes the normal anatomy, histology, and physiology of the suprarenal glands and the anatomy and pathology of suprarenal disorders. The first part, dealing with the anatomy and histology of the suprarenals, is comprehensive and well illustrated. The second part is devoted to a description of the physiology of the suprarenals, and contains adequate accounts of the effects of ablation of the suprarenals, the pharmacological action of adrenaline, and the cholesterin content of the suprarenal cortex. The third part is more important and also more controversial, for there the authors discuss the available evidence about the physiological functions of the suprarenal cortex and medulla. The function of the suprarenal medulla has been a matter of keen dispute during the last two decades. The problem is important because all views of the part played by adrenal insufficiency in pathological conditions depend very largely upon an underlying theory about the functions of the medulla in the normal body. The authors' account of these problems is interesting, but somewhat one-sided.

Fortunately there is no need for any writer on endocrinology to attempt a full bibliography of his subject; the third volume of Biedl's monumental work already provides more references than anyone could read in a lifetime. Selected references, such as are provided by the authors of the volume under review, should, however, be fair samples of existing evidence. In reading the third part, certain striking omissions in the letterpress led us to analyse the appended bibliography. There are 205 references: 110 French, 31 German, 28 American, 18 Spanish, and 18 from other nationalities. Moreover, half of the 90 foreign references are to work that is more than ten years old. These figures indicate pretty well the value of this section of the book. It gives a fair account of the classical work on the subject, and a good account of the recent French work, some of which has been very brilliant; but it deals inadequately with the great mass of work in connexion with this problem in recent years in other countries.

The fourth part is devoted chiefly to the pathological anatomy of diseases and tumours of the suprarenals; the fifth part, which is well illustrated, describes the suprarenal syndromes, including such conditions as Addison's disease, suprarenal hirsutism, etc. The sixth and last part is very much the shortest, for it deals with the therapy of suprarenal disorders, and unfortunately there is little that can be said on this subject.

THE SCIENCE OF NUTRITION.

WE have great pleasure in welcoming the appearance of a fourth edition of Professor GRAHAM LUSK's classical work *The Elements of the Science of Nutrition*.[5] When the author completed the third edition twelve years ago he announced his intention of not writing another. Fortunately the wishes of his friends have prevailed upon him to reconsider his decision, although he now announces that this is the final edition. Perusal of the volume explains the author's reluctance to provide many editions, for it is evident that the whole work has been very thoroughly revised, and that much of it has been completely rewritten.

The science of nutrition began with the quantitative study of the fuel value of foods, but during the last twenty years increasing attention has been devoted to the qualitative aspect of nutrition, and the study of the minimal requirements of essential constituents such as inorganic salts and vitamins. The attention of the author is centred chiefly on the quantitative aspects of nutrition, and only one chapter is devoted to vitamin and the biological value of various proteins. The work forms an exhaustive summary of the knowledge regarding the quantitative aspects of nutrition. Moreover, it is written in a clear and easy style, and its pages are enlivened here and there by the author's opinion regarding social and political problems.

[3] *Physical Therapeutic Technic*. By Frank Butler Granger, A.B., M.D., With a foreword by William D. McFee, M.D. Philadelphia and London: W. B. Saunders Company. 1929. (6 × 9¼, pp. 417; 155 figures. 20s. net.)

[4] *Traité d'Endocrinologie: Glandes Surrénales et Organes Chromaffines*. Par M. Lucien, J. Parisot, et G. Richard. Paris: G. Doin et Cie. 1929. (7 × 9¾, pp. 710; 104 figures. 100 fr.)

[5] *The Elements of the Science of Nutrition*. By Graham Lusk, Ph.D., Sc.D., LL.D., F.R.S.Ed. Fourth edition, reset. Philadelphia and London: W. B. Saunders Company. 1928. (6 × 9¼, pp. 844; 46 figures. 32s. 6d. net.)

As we have remarked, attention has been focused recently more on the qualitative than on the quantitative problems of nutrition. The enormous importance of the latter aspect of the science is, however, very clearly shown in some telling sentences with which Professor Lusk concludes his work.

"The annual value of food used by the people of the United States is at least $12,000,000,000. This is taken with little knowledge of what food really is. It has been thought by workers in the laboratory that it would be of great importance in times of poverty and distress to associate the calorie value of food with cost in dollars and cents. In the third edition of this book much was said upon this subject which need not here be repeated. Since that writing we have passed through a great crisis. It was a group of men within the Royal Society of London whose policy saved their country in 1917-18. Through the acceptance and support of that policy by the Interallied Scientific Food Commission the allied population of 225,000,000 individuals was maintained in good nutritive condition. . . .

"To build one battleship requires one thousand times more money than that useful nutrition laboratory spends in a year. As enlightenment grows, let us hope for fewer battleships and better supported laboratories. For in the words of Alonzo Taylor, 'The future social organization will be the product of the land, the population, the development of the arts and sciences, and the standard of living.'"

The last sentence is a quotation from Charles Richet, who wrote on his seventy-fifth birthday:

"Science, Patrie, Humanité, Justice—ce sont de grands mots et de grandes idées aussi; elles peuvent paraître démodées, mais je les chéris aujourd'hui et je les vénère comme au temps de ma lointaine jeunesse. Car ce sont les étoiles étincelantes vers lesquelles nous devons tous deriger notre course."

NOTES ON BOOKS.

THE fifth edition of Dr. HEITZMANN'S *Urinary Analysis and Diagnosis*[6] is a revision of the fourth edition published in 1921, and contains at the end a chapter on the functional efficiency of the kidneys by Professor Dannreuther. Two-thirds of the volume are devoted to the microscopical examination and diagnosis of urinary sediments, and this part of the book is illustrated with over 100 plates of drawings of the sedimentary objects, under the high magnification of 500 diameters in most cases, drawn by the author from specimens in his own possession. Dr. Heitzmann is convinced that textbooks pay insufficient attention to the possibilities of diagnosis by the examination of urinary deposits under the microscope, and endeavours to correct this faulty view in his book. The illustrations are excellent, and the volume is well turned out; it may be recommended to medical men and students anxious for help in the interpretation of urinary sediments and abnormalities.

Pharmaceutical Therapeutics,[7] by Dr. E. V. LYNN, is a textbook of pharmacology and toxicology written specially for students of pharmacy. It contains a short description of the pharmacopoeial drugs, together with an account of their chief pharmacological actions and their mode of employment in disease. A medical student would find this book quite a useful summary for revision purposes; its value to pharmaceutical students is, however, open to question. The author repudiates the suggestion that his book will tend to encourage "counter prescribing" by pharmacists, and claims that the pharmacist cannot fulfil his duties intelligently unless he has an accurate, even if incomplete, knowledge of the purposes intended in a prescription. He quotes the suggestion of a committee on the pharmaceutical curriculum that it is desirable that he may be aware of the dangers associated with ignorant or pathology, and is therefore unacquainted with the nature of the functions of the body in health and disease, can he never-theless understand how these functions are modified by drug treatment? The medical curriculum is based on the assumption that this is impossible. If we admit that a pharmaceutical student who has not studied the sciences upon which medicine is based can profitably study medical treatment, we thereby admit that the greater portion of the medical curriculum is superfluous. We are of the opinion that rational treatment must be based on a comprehension of the functions of the body, and therefore consider that the author of this book is mistaken in his belief that he can impart an elementary knowledge of therapeutics to persons who have not studied the basic sciences of medicine.

The fifth edition of *Artificial Sunlight and its Therapeutic Uses*,[8] by Dr. F. HOWARD HUMPHRIS, has now appeared. The previous edition was reviewed in our columns on August 11th, 1923 (p. 260). The author has taken the opportunity of introducing descriptions of the latest types of apparatus, and of revising the advances made in other respects. The new edition will increase the popularity of a useful handbook.

Colonel STEPHENSON'S translation of the *Zoological Section of the Nuzhatu-L-Qulúb*[9] offers the reader a popular educator in zoology as that science was understood in Persia some six hundred years ago by its compiler, the historian Mustaufi. It will be of interest to the student of zoological history because it gives a clear view of the poor quality of zoological science in the Mohammedan East in mediaeval times. The serious zoologist, on the other hand, will find it a disappointment, as it abounds, in statements lacking proof—thus, on page 59, it is asserted of the frog that "if its tongue be laid on the heart of a sleeping woman, she will tell whatever she may have done."

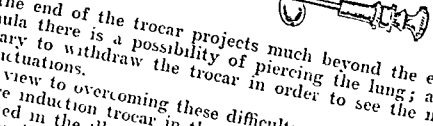
[6] *Artificial Sunlight and its Therapeutic Uses*. By Francis Howard Humphris, M.D.Brux., F.R.C.P.Ed., M.R.C.S.Eng., L.R.C.P.Lond., etc. Fifth edition. London: Oxford Medical Publications, Oxford University Press. 1929. (Demy 8vo, pp. xxi + 349; 31 figures. 10s. 6d. net.)

[7] *The Zoological Section of the Nuzhatu-L-Qulúb of Hamdullāh Al-Mustaufi Al-Qazwīnī*. Edited, translated, and annotated by Lieut.-Colonel J. Stephenson, C.I.E., M.B., D.Sc., F.R.C.S., I.M.S.(ret.). Oriental Translation Fund, New Series, Vol. xxx. London: The Royal Asiatic Society. 1928. (Demy 8vo, pp. xix + 93.)

PREPARATIONS AND APPLIANCES.

A Pneumothorax Induction Trocar and Cannula.

DRS. A. I. GRANVILLE MCLAUGHLIN and A. J. DIX-PERKIN (Tuberculosis Department, St. Thomas's Hospital, London) write: In the induction of pneumothorax with the Riviere trocar and cannula, it is necessary to push the instrument down as far as the parietal pleura, withdraw the trocar, and then push the blunt cannula through the membrane into the potential pleural space. This method is advocated in order to avoid damage to the underlying lung. In practice we have found it unsatisfactory, because considerable pressure is requred to push the cannula through the membrane; the parietal pleura tends to be stripped off the ribs, and there is a possibility of damage to the pleura and subsequent pleural shock. Further, if the pleura is not sufficiently anaesthetized the procedure causes a considerable degree of pain. We have found that the best way to use the Riviere induction needle is to penetrate the parietal pleura with the sharp trocar, which is then withdrawn. If the end of the cannula is in the pleural space the manometer shows wide negative respiratory fluctuations. If not, the trocar has to be reinserted and further search for the pleural space ensues. The disadvantages of this method are



that if the end of the trocar projects much beyond the end of the cannula there is a possibility of piercing the lung; and it is necessary to withdraw the trocar in order to see the manometric fluctuations.

With a view to overcoming these difficulties we have modified the Riviere induction trocar in the following particulars, which are indicated in the illustration. (1) The point of the trocar is made to project as little as possible beyond the end of the cannula. (2) The trocar is grooved from its point to where the shaft is narrowed. The narrowing of the shaft is continued to the point opposite the cannula's side projection, to which is attached the rubber tubing going to the manometer and the air reservoir. (3) The cannula does not have the lateral aperture which is a feature of the Riviere needle. The result of these modifications is that there is a continuous air space from the point of the needle to the manometer. Manometric fluctuations are set up as soon as the point of the needle enters the pleural space. The very short point of the needle practically precludes the possibility of damage to the lung. If necessary, air can be injected without withdrawing the trocar. The abolition of the lateral aperture does away with the possibility of air being injected at the same time into the tissues of the chest wall.

The instrument has been made for us by Messrs. Down Bros., St. Thomas's Street, London, S.E.1.

MEETING OF THE BRITISH ASSOCIATION IN JOHANNESBURG.

[FROM OUR CORRESPONDENT IN PRETORIA.]

By Wednesday, July 31st, all the members of the British Association for the Advancement of Science who were attending the meeting in South Africa had reached Johannesburg, and that night the inaugural meeting of the British and South African Associations was held at the City Hall. Mr. J. H. Hofmeyr, Vice-Chancellor of the University of the Witwatersrand, had already welcomed the visitors at Capetown as president of the South African Association. That night he welcomed them to Johannesburg, the centre of the busiest scientific and technical life of the Union of South Africa, a city which, he said, owed most to science, but which had not been remiss in requiting the favours she had received from the hands of science. The scientists of Johannesburg were proud of its industries, proud of its medical research, and proud of the achievement of its youthful university. South Africa was a thinly populated land, where the challenge to scientific work was urgent; workers had to carry on their activities in comparative isolation, and without the facilities for intercourse with which the older countries were so richly endowed. Chiefly they felt the want of such facilities with fellow workers in the scientific field. The opportunities provided by the present visit were therefore inestimable.

Minerals and Sociological Problems.

In his presidential address, which was entitled "The international relationship of minerals," Sir Thomas Holland surveyed the distribution of minerals throughout the world. He made the attractive suggestion that a world control of mineral output by the British Empire and America was practicable, and might be used to prevent future wars. As minerals were essential to the conduct of modern war, the world's peace would be most firmly secured by an addition to the Kellogg Pact whereby the export of minerals to belligerent nations would be prohibited. Only the United States and the British Empire possessed mineral resources sufficient to maintain a war for any length of time. The discussion of local mineralogical problems has naturally attracted most attention here. Hard-headed Johannesburg quickly recovered from its surprise at finding its visitors practical scientists, and not detached, absent-minded dreamers whose researches and discussions would do no more than contribute, perhaps, to the solving of world problems which might arise a century hence. Thus Professor J. S. Haldane proffered suggestions for making gold mining possible at really great depths, where the rock, and hence the atmospheric temperatures, reached body heat; these proposals excited interest throughout the length of the Witwatersrand. The discussions relating to the great gold-mining industry, with its economic, biological, and geological problems, must be given first place, but the groups of papers dealing with such important matters as native education and agriculture will undoubtedly considerably affect local measures and procedures for many a year.

Group Administration of the Gold Mines.

The organization of the thirty-three gold mines of the Witwatersrand into half a dozen corporations, with the greater resulting efficiency, was expounded by Mr. John Martin, chairman of the Transvaal Chamber of Mines, before the Economic Section. It was adequately proved that this system of group control was based upon a correct conception and an effective application of sound principles of industrial management and administration. Very great benefits had accrued to the mining industries in the Transvaal by this system, which had been brought into being by sheer necessity. The largest of these corporations or groups controlled fourteen of the mines. Among the many services that the group system performed was the organization of medical services. The largest group had a centralized health department under highly qualified professional direction, to which was entrusted the business of supervising, assisting, and co-ordinating medical and hygienic practice in the mines and in the native compounds. Mr. Martin further outlined the centralization of the mines as represented by the Transvaal Chamber of Mines and the two co-operative corporations allied with it, which undertook all the recruiting and provision of native labour for the mines—one from British South Africa, the other from Portuguese Africa. Very few of the gold mines of the Witwatersrand could exist except upon the basis of the bulk of the physical labour being performed by natives, who throughout the gold-mining industry were employed in relation to white employees in the ratio of about nine to one. The conditions of employment for natives in the industry—taking wages, food, accommodation, and medical attention into consideration—represented outstandingly the best standard in South Africa under which native workers were employed in large numbers. The recruiting corporations had an enormous field to cover in arranging for a regular and adequate flow of labour. The natives, before being engaged at their homes, were medically examined; the terms of their engagement were embodied in a contract which was explained to them by the magistrate of the district; and transport from remote parts had frequently to be provided. On arrival at Johannesburg the natives were accommodated at and passed through the great central compound—a compound which had received over 1,250,000 natives in the last ten years—and after all matters concerning passes and passports and further medical examination had been attended to they were sent to the mines for which they had chosen to work, or to which, with their consent, they had been allotted. Further arrangements were also made for repatriation to their homes when their periods of service had expired. While the natives were in employment their interests received organized attention; if they became ill they received the best hospital and medical treatment. The hospital accommodation for natives on the gold mines—provided by the mines themselves—consisted of fourteen separate hospitals with some 2,400 beds. An enormous organization had been built up for dealing with compensation for injuries to employees; more than a million and a quarter sterling had been paid out by the corporations to white workers since the Workmen's Compensation Act came into force in 1915.

Dr. G. C. Allen voiced the interest aroused in the visiting economists by Mr. Martin's paper, because while the immediate subject was local the principle was world-wide. South Africa seemed to be a particularly genial field for combinations. The gold industry had succeeded in securing economies in production costs which in practice were so seldom secured. The idea of the group organization was not confined to the Rand, but was a general tendency in most of the countries of the world, but in practice combinations of this type had been less successful in England than was apparently the case here.

Professor Clay remarked that the difference in the position on the Rand and in England could be gauged by the fact that while in the gold mines a contribution of 6s. a shift could be made for miners' phthisis funds, it took the coal industry all its time to pay a little more than 6s. a shift in wages.

The Hygiene of Deep Mining.

Gold mining is now being carried out on the Rand at depths exceeding 7,000 feet. Mining a low-grade ore with profit at these great depths not only raises great engineering difficulties, but with present hygienic methods is becoming almost impossible. Hitherto silicosis preventive measures underground have consisted largely in laying of the dust by wet methods of mining. This results in a virtually saturated underground atmosphere. At great depths the high temperature, combined with a saturated atmosphere, prevents cooling of the body, rendering muscular effort without grave danger impossible. It is evident, therefore, that if mining is to be carried out at still greater depths some other method of silicosis prevention will have to be devised. It was to this problem that Dr. Haldane's paper entitled "The avoidance of silicosis with dry methods of working" made valuable contribution. His animal experiments suggested that it would be possible to work by dry methods, if such precautions were taken that the larger quantity of silica dust which would then be inhaled was mixed with another kind of dust possessing the property of neutralizing the ill effects of the

silica. Thus the quartz in shale dust with 60 per cent. of total silica did not produce phthisis. Shafts, inclines, and open levels should be kept dry and stone-dusted with the added dust; suitable apparatus for applying the dust was already available. Drills should be provided with efficient dust-collecting arrangements, so that the men could not inhale the unmixed dust. Lastly, all blasting should be so arranged that a sufficient quantity of the diluting dust passed into the air, and was scattered over surrounding surfaces, with each shot. In this way stopes and drives would be kept dusted with the diluent dust, and any dust present in the air would be neutralized.

Professor Haldane's paper was discussed at a joint meeting of the physiology and engineering sections. Dr. A. J. Orenstein, superintendent of sanitation, Rand Mines, Ltd., pointed out that work in temperatures which would ordinarily be considered moderate caused physiological strain, which not infrequently resulted in heat stroke if the air was near saturation point. The majority of cases of heat stroke occurred, however, among newly engaged labourers, showing that acclimatization was an important factor. It was now the practice to put new labourers for the first week or two in relatively cool places, gradually acclimatizing them to work in the hotter places. Dr. H. Pirow, Government mining engineer, sounded a note of warning regarding the suggestion that the dangerous silica dust might be dealt with by dry methods. It would be deplorable if this suggestion were wrongly interpreted to mean that the extensive use of water could be restricted before some definite and practical method were put in its place.

Archæological Investigations.

Miss Caton Thompson (leader of the research party of the British Association which had been sent to Rhodesia in advance to study the Great Zimbabwe and other ruins) would appear to have disposed finally of the fascinating theory, popularized by Rider Haggard, that South Africa was the source of King Solomon's gold. Having studied the ruins it was inconceivable to her how a theory of Semitic or civilized origin could ever have been foisted on a credulous world. Every detail in the haphazard building, every detail in the plan, every detail in the contents, apart from imports, appeared to her to be typically African Bantu. It was also inconceivable to her how a theory of antiquity in the sense of Oriental archæology could ever have been formulated by observant people. The structure of the buildings was such that not one stone would be standing on another in a period reckoned in millennia and not in centuries. Her respect for and interest in the Rhodesian ruins was enormously strengthened thereby. Instead of being a degenerate offshoot of a higher Oriental civilization, best studied in its homeland, they had, she believed, a vigorous native civilization, unsuspected by all but a few students, showing national organization of a high kind, originality, and amazing industry. It was a subject worthy of all the research South Africa could give to it; South African students should be bred with the purpose of pursuing it.

Honorary Degrees.

The University of the Witwatersrand conferred honorary doctorates on seven of the visiting scientists. The recipients included Sir Thomas Holland, president of the British Association, and Professors J. S. Haldane, J. C. Myres, and D'Arcy Thompson. The capping ceremony was performed by Mr. J. H. Hofmeyr, Vice-Chancellor of the University, who referred briefly to the ten years' work of one of the youngest universities in the world. Southward the University looked over the line of mine dumps; northward across miles of rolling veld. "Not least of the tasks of this University," he said, "is to bring into conjunction mining and agriculture, Rand and Platteland, English-speaking town dwellers and Dutch-speaking country dwellers, the resources of established industry, and the opportunities of the land remaining yet to be possessed. And in respect of that task also it can point to an achievement of increasing significance." He recalled the time, ten years ago, when the University site was "a bare, windswept hillside, a disused stone quarry." They were met within the theatre of these great buildings to inscribe upon the roll of the University of the Witwatersrand some of the greatest names in the world of learning. Surely they could have wished for no better consummation of their ten years' work than that they should be honoured by the entrance into the fellowship of the University of men such as Eddington and Haldane, Holland and Molengraaff, Myres and Parsons, and D'Arcy Thompson.

THE SCIENTIFIC STUDY OF SEX PROBLEMS.

INTERNATIONAL CONGRESS OF THE WORLD LEAGUE FOR SEXUAL REFORM.

THE third International Congress of the World League for Sexual Reform, to which reference was made in last week's issue (p. 508), remained in session from September 8th to 14th. Sanitätsrat Dr. MAGNUS HIRSCHFELD (Berlin) presided. The organizers of the congress tried as far as possible to group together papers dealing generally with the same subjects, and sessions were devoted accordingly to the discussion of marriage and divorce; venereal disease and prostitution; birth control, sterilization, and abortion: sex and the censorship; sex education; and the treatment of sexual disorders. The following report of the proceedings is only a brief summary of a few of the papers of medical interest which were read in the various discussions.

The Premarital Consultation

Dr. A. STONE (Medical Officer to the Venereal Division, Department of Health, New York City) contributed to the discussion bearing on marriage and divorce a paper on premarital consultation. Many of the difficulties of conjugal life, he said, had their inception in physical or mental maladjustments, not a few of which could be prevented by timely medical care. An important step to this end would be a premarital examination for every man and woman, and many countries and States had already enacted laws making such examinations compulsory. The approach, however, had hitherto been only from the eugenic standpoint, the motive being to prevent the transmission of hereditary diseases. Dr. Stone suggested that this procedure involved too limited a conception of the function of premarital examination, which, in his view, should deal not merely with the racial factors of marriage, but with those of its aspects which affected the well-being of the individual couple. The object of the physician should be to seek out potential maladjustments, to suggest preventive measures, and to instruct the couple in a rational hygiene of their sexual life. For this purpose the physician should inquire into the patient's family and personal history, with particular reference to the sexual history; make a general physical examination, paying special attention to the reproductive organs; examine the seminal fluid so as to exclude azoospermia; and, in the female, look for conditions which, if uncorrected, might lead to dyspareunia. Furthermore, it was important to determine the condition of the uterus and adnexa, having special regard to the possible presence of an infantile uterus, fibroids, displacements, or other abnormalities which might be significant in relation to the fertility of the individual. A Wassermann test should be made in the case of every person applying for premarital examination.

Venereal Disease.

Discussing the prevention of venereal disease, Dr. WANSEY BAYLY asserted that immediate self-disinfection had been proved conclusively to be an effective preventive measure; indeed, in 1919, representatives of the Admiralty and War Office had agreed that the ultimate elimination of venereal disease depended not on treatment after infection, but on prophylaxis after exposure. Venereal diseases, says Dr. Bayly, would long ago have become only a memory, or at worst a pathological curiosity, in civilized countries if the bulk of thought about this infection had not become enmeshed in the all-powerful sexual taboo. Much mischief had been done by misguided persons who, under the pretext of protecting the public against quacks, succeeded in inserting in the Venereal Diseases Act, 1917, a clause whereby it was made an indictable offence to expose prophylactics for sale, or to include with prophylactics sold over the counter directions for their use. Even more fantastic was an organization which in its early publications permitted the recommendation of a very mild, and therefore ineffective, prophylactic, but forbade the recommendation of permanganate solution, which happened to be effective.

Birth Control.

The discussion on birth control was opened by Dr. MARIE STOPES, who reminded the congress that she and her husband had founded the first birth control clinic in the British Empire. When the clinic was first opened only 1.7 per cent. of the women who attended had abnormalities of the genital tract; this proportion steadily increased, rising in the second year to 15 per cent., then to 39 per cent., and recently to 44 per cent. of all patients. She attributed this extraordinary change to the fact that during the early years the spread of knowledge brought about by the work of the clinics, and by the increasing availability of literature on the subject, had rapidly exhausted the supply of normal women requiring information, leaving a preponderance of women with abnormalities. Dr. C. V. DRYSDALE, president of the Malthusian League, summarized the chief advantages of contraception as (1) improvement of the economic status of the family and nation without depriving the married of sex union; (2) reduction of strain on women brought about by too frequent childbearing; (3) opportunity for better care and education of each child; (4) opportunity for limiting reproduction of defective types; and (5) increasing facility for early marriage, and thus elimination of much sex repression and temptation to sexual irregularities. Against these advantages he set (1) the possible injurious effects of contraceptives to men and women; (2) the possible decay of parental feeling, or, alternatively, an excessive coddling of small families; (3) increase of promiscuity through removal of fear of consequences. Dr. Drysdale cited a great deal of statistical evidence tending to show that the frequently expressed fear of physiological danger attending the practice of contraception was without foundation. For over half a century, he said, there had been a declining birth rate, yet almost every year the Registrar-General reported that the death rate was the lowest ever recorded. The correspondence between the decline of the death rate and that of the birth rate was one of the most striking phenomena of our time. Dr. ERNST GRÄFENBERG (Berlin) described his intrauterine contraceptive appliance, which, he was careful to point out, was not, as were certain rightly condemned appliances, placed within the cervix, but within the cavity of the uterine body itself. There was thus, except at the moment when the appliance was inserted or removed, no danger of ascending infection of the genital tract. The advantages of the method were these: it could be applied only by a physician, and its application remained always within his control; once the appliance, a ring of silver wire, was inserted in the corpus uteri it could remain *in situ* for a year, or even longer. Moreover, said Dr. Gräfenberg, the method was reliable, not injurious, and not attended by the aesthetic disadvantages involved in the use of every other contraceptive device. Contraindications were few in number, and included inflammations of the genital tract, menorrhagia, and submucous fibroids. The speaker added that this method had been extensively, and successfully, used in Germany. It represented what might prove to be a most important advance in the technique of contraception, and as such it merited, he thought, the fullest investigation. Dr. HANS LEHFELDT (Berlin) said that the qualities to be desired in a contraceptive were reliability, innocuousness, cheapness, unobtrusiveness, and simplicity. He condemned the production of temporary sterility by means of x rays on the grounds that the method was unreliable and likely to bring about a premature climacteric. Moreover, it was sometimes responsible for the production of congenitally abnormal children. On similar grounds he suggested that at present contraceptives based on the use of spermatoxins were to be condemned. After considering Gräfenberg's method, which he suggested had the disadvantage that removal of the silver wire was sometimes difficult, he analysed the various contraceptive procedures involving the use of cervical caps and occlusive pessaries. He criticized the former on the ground that, however easily adjusted, they were liable to be dislodged during coitus; and of the latter he preferred a Dutch pessary, used in conjunction with a non-greasy jelly so constituted as not to interfere with the normal chemistry of the genital secretions. The ideal contraceptive, he claimed, had yet to be discovered. Dr. NORMAN HAIRE said that during the past ten years he had taught contraceptive technique to over 7,000 persons, many of whom had remained under his observation. Until recently he had believed that the only method to be highly recommended was that which involved the use of a rubber occlusive pessary associated with a lactic acid jelly. His investigation of Gräfenberg's method had convinced him, however, that for certain patients it was quite as valuable as the combined method, and, indeed, for some patients it was more valuable. The silver ring, he said, could easily be introduced by any medical practitioner; the patient might feel slight discomfort at the moment of its introduction, but not afterwards.

Sterilization.

In the discussion of this subject Dr. HAIRE said that public opinion should be educated so that as far as possible unfit people might voluntarily submit themselves to sterilization. Persons who persisted in exercising their procreative powers to the detriment of society and the race should be the subjects of compulsive legislation. Dr. M. D. EDER held, on the contrary, that those who had the most knowledge of this matter—for example, some members of the Mental Deficiency Committee—were not very sanguine about extinguishing inherited defect by way of sterilization. Defective children born of defective parents did not form a large proportion of defectives existing. The distinction between heredity and environment was not so sharply defined as many persons liked to imagine. The factors of inheritance were indeed extremely complex, and biologists were very far from having obtained results which could with certainty be applied to man. Social reformers must not hurry on their experiments on the large scale when science could offer them no guidance. Biologically speaking, sterilization would not appreciably lessen the number of the feeble-minded, though it might reduce the production of individuals with talent or genius. Suggesting a psycho-analytical interpretation of what he called this enthusiasm to sterilize, Dr. Eder said that there were in man primitive filicidal impulses which, though held in check, were not abrogated. These impulses were being sublimated into the promotion of legislation for the sterilization of other people's children. He urged on the conference the need for vigilance and activity to prevent further restrictions on liberty and to remove many restrictions already existing; to press for investigation rather than imprisonment, and for freedom rather than restriction. Let mankind grow, he concluded, even if it makes mistakes.

Abortion.

Dr. A. GENS (Russia), in his contribution to the discussion on abortion, said that the Soviet Government was fully alive to the evil resulting to the community from the practice of secret abortion. It combated this evil by conducting propaganda against abortion among the masses, and envisaged its disappearance as the principles taught by the Society for the Protection of Motherhood and Infants became more widely spread. The people's commissariats of public health and justice, holding that repressive measures would fail to achieve the protection of women from ignorant charlatans, had decreed the following: (1) abortion might be performed free in the Soviet hospitals; (2) nobody but a doctor was entitled to perform the operation; (3) midwives guilty of procuring abortion were to be deprived of their right to practise and criminally prosecuted before a people's court; (4) a doctor who procured abortion for remuneration by way of private practice was to be criminally prosecuted before a people's court. Dr. HAIRE suggested that there was no moral objection to abortion in itself; whether an abortion was justifiable or not depended on the circumstances of the individual case. He did not think that abortion was to be recommended lightly and without the most serious consideration; it involved interruption of a physiological cycle, and could not be without unfavourable effect on the woman's health. It was simply a question of which in the individual case was the more harmful—the abortion or the continuation of the pregnancy. The law which forbade abortion had to be obeyed, but it would be an advantage if the law were changed. Dr. EDER was of opinion that the legislative code of some Scandinavian countries might be adopted, whereby at the woman's request abortion could be performed during the first three months of fœtal life. Such operations should not take place without the sanction of two medical men and the concurrence of the medical officer of health. He reminded the congress, however, that so much was obscure in the psychological attitude of men and women towards their desire or fear of parenthood that adequate safeguards would have to be imposed to prevent abortion from being too lightly undertaken.

British Medical Journal.

SATURDAY, SEPTEMBER 21ST, 1929.

SURGICAL TUBERCULOSIS.

THE first discussion in the Section of Orthopaedics at the Annual Meeting of the British Medical Association at Manchester was concerned with the indications for operative treatment in tuberculosis of the larger joints and the results which follow. This topic was particularly well chosen, for it is clear that the time has come when an effort should be made, so far as imperfect data may permit, to draw up some sort of a balance sheet of the present position as regards the cure or relief of tuberculous joint diseases by the methods which have come into vogue and been practised all over the country since the beginning of the century. In the latter part of the last century general surgeons were attempting to cure tuberculous joints by radical operations such as excision; they paid little attention to any but the localized manifestations of disease, and with the hospital accommodation then at their disposal were unable to treat the constitutional condition effectively. The small band of orthopaedic surgeons, however, were accustomed to treat tuberculous disease of the large joints of the lower extremity on the principles of Hilton and Thomas by means of rest and fixation, being content if in the end they obtained fibrous ankylosis in a useful position. When, in later years, these methods were associated with open-air and sunlight treatment, both in Europe and in America, much better results followed, and most surgeons accepted the new teaching. Of late, owing to the widespread adoption of the methods advocated by Sir Robert Jones and the Central Committee for the Cure of Cripples, which include clinics for after-care scattered about the country, it has become possible to ascertain what becomes of the "cured" tuberculous joint after discharge from hospital, and some searchings of heart have followed on inquiries. A distinguished French surgeon—Dr. Calvé of Berck-sur-Mer—has said of these cases, rather cynically, "When the disease is cured, then the troubles begin." Although such a sweeping generalization must be taken with a good deal of salt, there is enough truth in it to make us lay it to heart as an antidote to excessive optimism.

Some surgeons, and among them the opener of the discussion, who has been one of the most successful followers of the most modern methods, have been able to keep in touch with patients after discharge from hospital, and to formulate some definite statements as to ultimate results, or at least of results up to six years after discharge from hospital. At the outset it is necessary to state that tuberculosis of a joint in an adult is a far less hopeful and more fatal disease than this condition in a child, and that such cases are seldom satisfactorily treated by conservative methods. What was said in the discussion at Manchester, and the comments now to be made, must be taken as referring to children and young adolescents. Moreover, since the hip-joint is so often the seat of disease, and its integrity is so important, it may fairly be assumed that many, or even most, speakers and writers have this joint in mind when they generalize on the subject.

Mr. Girdlestone stated in *The Robert Jones Birthday Volume* (p. 369) that in children conservative treatment of the hip often led to free movement. Mr. C. Lee Pattison, in his paper which is printed in this issue at page 532, deals with 300 cases; he claims in an analysis 167 cases as showing an almost perfect functional result with an almost completely full range of movement, no shortening, and no sign of disease, when examined after (on an average) the lapse of 65.5 months since discharge. He thinks, however, that among these 167 cases there may be some of transient arthritis which have been labelled tuberculous in error. Even so, these are very remarkable records, for when we come to survey American experience we find a startling contradiction. Drs. Smith and Watters (quoted by Mr. Girdlestone from the *Journal of the American Medical Association* for January 21st, 1928) can only record two cases out of 208 which "were free from symptoms and had a useful range of motion"—and even these are not stated to have *normal* mobility. Dr. F. C. Kidner of Detroit, in a paper read before the Section of Orthopaedic Surgery at the seventy-ninth annual session of the American Medical Association in June, 1928, asserted his belief that this disease was never cured with useful motion when cartilage or bone was involved; he thinks the question of the existence of a type of tuberculosis of the hip which involves only the synovia and does get well is still open to discussion. He holds that it is only possible to explain the contradictory results in America and Europe on the hypothesis of a difference of the virulence of the infection on the two sides of the Atlantic. From these facts we must conclude that more light on the subject is required, and that until a longer and wider experience is available it is unsafe to draw conclusions.

Mr. Girdlestone, whose paper on operative treatment in tuberculosis will be found at page 529 of this issue, defined the part the surgeon could play in the treatment of tuberculous joints, and the time which he should choose for doing so. When unable to secure free movement the surgeon should try to procure firm bony ankylosis or an extra-articular arthrodesis. It is somewhat remarkable that one with such a long experience of the conservative treatment of hip disease at the Wingfield Orthopaedic Hospital should be constrained by his experience and an open mind to write: "At present I feel that the solution lies in early radical excision and late grafting. And in certain types and older ages I think amputation is indicated." Sir William de Courcy Wheeler, who followed Mr. Girdlestone in opening the discussion, brought to the debate the experience and judgement of a distinguished general surgeon. Perhaps his saying that the pendulum of the surgical clock swings erratically, and its hands often move backwards, may be taken as a valuable reminder that we should look backward as well as forward when trying to make progress in any department of surgery. Mr. Girdlestone remarked that we could not afford to allow open air and rest to become discredited. To this it might be rejoined, with Sir Robert Jones, that it is homage, and not allegiance, that should be paid to any method of treatment. Dogma should have no place in surgery, and if it should be shown (which seems most unlikely) that open air and rest were no longer needed in treatment, then it would become necessary to discredit them. The officers of the Section are therefore to be congratulated on their selection of this important subject for the first sitting at Manchester; gratitude is due also to those who made valuable contributions to the debate. Free and frequent discussion of abundant facts can alone cause sound methods of treatment to evolve, to endure only until better are found.

THE DECLINE IN THE ART OF PRESCRIBING.

TO-DAY, as in all former times, the impulse of sick humanity is to seek relief from pain and discomfort in medication of one kind or another. While, however, advances in biochemistry and pharmacology are making available to the practising physician a multiplicity of drugs more effective than any used in the past for the alleviation of pain and cure of disease; while, moreover, it is becoming increasingly possible to administer drugs not merely empirically, but scientifically, with due regard to their uses and limitations, the art of prescribing appears to be undergoing a steady decline. The old gibe, that the doctor puts drugs of whose action he knows little into a body of which he knows less, has lost much of its sting. Yet, paradoxically enough, skill in the administration of medicaments is in danger of passing just at a time when science has brought to the physician's aid drugs of known composition and proved efficacy.

While the value of certain specific remedies is not disputed, there has been a tendency in some quarters to cast doubt on the efficacy of drugs in the treatment of common and minor ailments. In so far as such scepticism has discouraged penny-in-the-slot medication it has been all to the good. But these minor maladies mean much to the patient, and he not unnaturally expects his doctor to apply every available method for their relief. The practitioner who has studied the art of prescribing, who possesses a thorough knowledge of the properties and actions of everyday drugs, who puts no trust in routine formulae but writes his prescriptions to meet the requirements of each individual patient, may, indeed, in the treatment of such maladies, achieve successes as dramatic as any that are attained by the use of specific remedies. An austere disbelief in drugs can be carried too far for the patient's comfort and well-being. Let us by all means welcome the shifting of emphasis away from the "bottle of physic," and towards diet and regimen; but let us not mistake ignorance of how and when to order well-tried remedies for therapeutic enlightenment. Drugs have as great a value to-day as ever—greater, indeed, by reason of the more accurate knowledge which pharmacological research and clinical study have given us regarding their mode of action and their efficacy in varying circumstances. But a good drug is worse than useless if ill chosen and ill administered. It may not be out of place to recall a story told by Dr. Haythorne in one of his *Medical Essays*. "'Drugs, I suppose, are no use,' once remarked a distinguished surgeon in consultation with an equally distinguished physician. 'Not the slightest,' was the somewhat unexpected reply, 'unless you know how to use them.' There is in this incident a moral that ought not to be lost by the superior person who professes to have 'no faith in drugs.'"

The decline in the art of prescribing may to some extent be explained by failure on the part of the medical schools and of the various examining bodies to give due weight to the importance of the subject. Another factor is the widespread habit of relying on the stock prescriptions set out in formularies. Noteworthy also is the growing tendency to substitute for the skilled and rational use of therapeutic agents the administration of powerful drugs in compressed form, and of proprietary preparations. It cannot be denied that a considerable number of such drugs and blends of drugs have their uses, but they have a twofold danger: not only is the busy practitioner tempted to prescribe them almost by rule of thumb, but the ready facility with which so many of them may be obtained by the public is in large measure accountable for the increasing practice of self-medication. Members of the public who on their own responsibility take such drugs for the relief of pain do so without realizing that the same symptom may be due to many different causes, and that removal of the cause of the pain is far more important than removal of the pain itself. This practice is the more to be deplored since it frequently deters the sufferer from seeking medical advice until the morbid condition underlying his pain or discomfort has become well established, and for that reason more difficult to cure. Still more to be regretted is the fact that proprietary preparations are too often ordered by medical practitioners with little personal experience of their value and possible dangers, and in some cases with little or no knowledge of their composition.

The factors which make for success in prescribing may be classified as follows: (1) an intimate knowledge of the therapeutic uses of drugs and of their doses; (2) avoidance of incompatibility; (3) the administration of nauseous drugs in a palatable form. The practitioner need not employ a large number of drugs; more important is it that he should know the action, uses, and doses of those he does prescribe. New remedies may certainly be tried, but caution must be exercised before old and proved drugs are abandoned for new ones. It may be admitted that incompatibility of ingredients could be avoided entirely by prescribing a single drug, but combining a drug with others possessing a similar mode of action often adds greatly to its efficacy. Students and practitioners who need practical guidance on this matter, in its chemical, physical, and pharmacological aspects, will find what they want in Dr. Thomas Stephenson's little book on incompatibility, of which a new and revised edition has just appeared.[1] Finally, it is to the prescriber's discredit if he orders a drug or combination of drugs in an unpalatable form. Patients nauseated by repulsive mixtures have been induced to take refuge in proprietary products, which in general are elegantly compounded. It is not our present purpose to discuss the pharmaceutical problems which may confront the practitioner, but we may end by recalling that in the *British Pharmaceutical Codex* he has a reference volume likely to prove of much value in maintaining his prescribing at a high level.

LONDON WATER, 1928.

In his annual report on metropolitan water for 1928[2] Sir Alexander Houston presents an interesting survey of the Thames as a source of water supply, reviewing at the same time its topographical interests and historical associations. The area of the watershed is 5,405 square miles; the average velocity of the river at Teddington is 1½ miles per hour. The maximum natural recorded daily flow is 20,236 million gallons, and the corresponding minimum figure is 155 million gallons. The average daily extraction for waterworks purposes is 152 million gallons. Though the Thames is contaminated by charges of sewage, many of which are of substantial quantity, the pollution as the river flows on is continually being diluted with pure underground water from the gravel and chalk, so that an automatic purification

[1] *Incompatibility in Prescriptions and how to avoid it.* With a Dictionary of Incompatibilities. By Thomas Stephenson, D.Sc., F.R.S.Ed. Edinburgh: "The Prescriber" Offices, 6, South Charlotte Street. 1929. 4s. 6d. net.

[2] Metropolitan Water Board. Twenty-third Annual Report on the Results of the Chemi[illegible]ation of the London Waters for the Tw[illegible]31st, 1928. By Sir Alexander Houston. Metropolitan Water Board. London: P[illegible]. 1s.

takes place, especially in summer, when many pollutions from the surface are unable to reach the river direct, and the ground water constituent predominates in consequence. The purity of the gravel and chalk water has been confirmed by examination. The gravel water at Sunbury, when systematically tested in 1925, showed *B. coli* absent from 100 c.cm. in more than 50 per cent. of samples. Chalk waters were examined in 1928 from eighteen points, mostly springs, in the watershed up to the head springs of the Windrush, with the result that in eight samples *B. coli* was absent from 100 c.cm., while all the rest compared most favourably with the ordinary water of the Thames. Reference is made to the practical importance of maintaining a high standard of purity in the prefiltration waters, the bacteriological summaries of which are tabulated for the year. It is shown that the percentage improvement in the quality of Thames water produced by storage alone, as measured by the presence or absence of *B. coli* in samples, was from one hundred- to one thousand-fold. Derived as they are from the great bodies of water contained in the various storage reservoirs, samples of stored water are more broadly significant than those taken, for example, from a filter, the integrity of which is subject to modification from hour to hour, and satisfactory bacteriological findings regarding them may be taken to imply a high degree of safety, from the epidemiological point of view, for the water as a whole. The results of the Barn Elms experiment, in which roughing filters without coagulant precede sand filters worked at higher speeds than normal, are brought down to the end of 1928. The final product is practically as good as that obtained by ordinary slow sand filtration. There has been comparative freedom from trouble due to algae or suspended material, and an increase in the output of water per acre of filtration area, allowing for the space covered by the roughing filters, per unit of time. In connexion with the action of frost and floods, which interfere with filtration and storage, it was found possible to supplement inadequate purification by filters by sterilizing large volumes of filtered water by means of emergency chlorination plant at little cost. In May and June the filtered water of the Stoke Newington works was found to be relatively unsatisfactory, and chlorination was decided on. Laboratory tests having demonstrated that the quality of the water was such that chlorination affected its taste, dechlorination was first attempted by the use of permanganate. Complaints were received of a brown colour produced in the water by the permanganate. The course then adopted was to add ammonia first and chlorinate thereafter; this plan was entirely successful. Reference is made to a vast concourse of seagulls which visited the Barn Elms reservoirs. These reservoirs, though in the metropolis, lie in a most secluded spot bounded by the river, some waste land, and the grounds of the Ranelagh Club. Seen on a day in January, the birds were swimming so close together that the whole stretch of water seemed covered with snow. They were ultimately scared off by gunfire repeated on a number of evenings. The contamination resulting from the presence of the birds was such that *B. coli* was found in 1 c.cm. of water. It was thought advisable to employ chlorination, after which *B. coli* was absent from 100 c.cm. The usual objection to the fouling of drinking water by birds is that it obscures the bacteriological picture, rendering it impossible to detect contamination by sewage, should such be present. The author raises the question whether the presence of gulls may not constitute a danger in itself, and cites the work of an observer who claims to have isolated *B. typhosus* from their excreta. Examinations made of the excreta of gulls frequenting the works of the Metropolitan Water Board gave uniformly negative results. In the emergency described the chlorination of the water was a wise precaution.

THE LEAGUE ASSEMBLY.

PEACEMAKING, like war, has its casualties, writes our correspondent from Geneva, and if the tenth Assembly of the League of Nations continues as it has begun, in torrid weather, and under conditions of overcrowding which have to be experienced to be believed, it will leave its mark on the health of the delegates. Little wonder that Dr. Stresemann has thought it well to bring with him from Berlin, not only his chef, but his medical adviser. The German Foreign Minister, who has the appearance of a very sick man, fortifies himself at intervals from some decoction in a glass in front of him as he listens patiently to interminable orations. The chief restorative, however, for all concerned would be a breath of fresh air. The assembly hall from which the delegates address the world at large would be, perhaps, a passable parliament house for a seventh-rate principality, but when it is called upon to accommodate the elect of more than fifty nations—there are three more than usual this year, Bolivia, Honduras, and Peru having returned to the League after a period of virtual severance—it can almost be described as a death-trap. The moral and spiritual atmosphere may be everything to be desired, but the physical atmosphere assails the senses in warm, even nauseating, billows. A very pretty system of ventilation—a sort of pop-gun arrangement—has been installed, and has every recommendation except adequacy. The crude resort of the Anglo-Saxon would be to open the windows, or, rather, the skylights, but this would disturb the delicate balance of the ingenious ventilating system, and so the frying-pan conditions remain unabated. On Saturday several intending orators, owing to sheer exhaustion, withdrew their names, and the delegates went in a mass to Ariana Park, on the outskirts of Geneva, where the foundation stone of the new building of the League was laid. In this fine park there will presently rise a dignified home for the League (which has hitherto made shift in a hotel) far exceeding in dimensions and grandeur the Peace Palace at The Hague. The site chosen is slightly east of the International Labour Office, itself a noble building, and from its high ground a series of terraces will lead down to the shores of the lake at a point where a perfect view of Mont Blanc and other of the Savoy Alps is obtainable. The sum voted for the site and buildings is £800,000. The British Government is interesting itself in the acoustics of the new assembly hall, and has offered to bear the expense of a series of experiments, to be carried out by the Department of Scientific and Industrial Research. One of the technical members of the building committee, accompanied by two of the five architects responsible for the structure, is to visit London in order to continue the study of this important question in consultation with British experts. Apart from the usual series of speeches addressed to the world at large by the representatives of different countries, very little real business was transacted during the first week of the Assembly. One matter taken up was the report of the International Institute of Intellectual Co-operation in Paris, to which nineteen countries now make an annual subsidy. The League Committee has adopted a rather ambitious programme, but its immediate objectives are the establishment of inter-university relations, the equivalence of diplomas, the co-ordination of bibliographies, and the preservation of classical works in the lesser-known languages. A list of holiday courses at European universities has been prepared, arrangements have been made for interchanges of visits of university staffs, and preparations are in hand for an international congress of publishers. The ever-widening work of the Health Organization has yet to be passed in review, but already several delegates, especially from South American countries and from India, have spoken in high praise of this side of the League's activities.

OCULAR ADAPTATION TO DARKNESS.

IT might be thought that the phenomenon of the adaptation of the eye to darkness was a subject of purely academic interest, of considerable theoretical importance to the physiologist, but little to the man in the street. The artificial conditions under which we live, however, are bringing, one after another, many of these so-called academic studies to the forefront of practical politics; and such common practices as motoring, or even flying, by night have made it of capital importance to study the ability of the eye to discern objects in low intensities of illumination. Moreover, there are many cognate questions of equal interest, such as the rate of visual recovery after the relative blinding following an exposure to a bright light for a short interval in darkness. It is well known that in passing from light into darkness vision appears to be completely lost; it then gradually returns, until, after a considerable length of time, details of objects can be made out with surprising accuracy. This process is known as "dark adaptation," and is due to an increase in the sensitivity of the retina. The final sensitivity of the dark-adapted eye is many times its actual value at the onset of the process; the rate at which this takes place and the degree of efficiency that is ultimately reached vary very much as regards individuals, but adaptation to the new conditions is accomplished to a great extent within the first few minutes, although the changes continue for a period averaging half an hour or more. The phenomenon not only affects white light, but is also evident in the discrimination of colours. At first, on being plunged into darkness, there is a definite "colourless interval," during which coloured lights of low intensity are seen achromatically, and the colour only becomes apparent when the intensity of the light is increased. As would be expected, visual acuity falls very considerably in the dark-adapted eye, and there is a considerable difference with regard to the degree of visibility of various colours. It is noteworthy, for instance, and it is of practical importance, that the minimal visual acuity for a red light is much less than for a white light. Different parts of the retina react differently. In poor illumination indirect vision appreciates small objects of low brightness more readily than direct vision, for in the dark-adapted eye the fovea itself is relatively insensitive: the most sensitive area is that immediately surrounding the macula. This may be verified in a rough-and-ready way by looking at the stars on a clear night, when a small star may be observed slightly to one side of the direct line of vision, but when the gaze is turned directly upon it it apparently disappears. It seems that this variation depends upon a difference in the functioning of the rods and cones, and, in so far as acuity of vision in the dark is concerned, the rods are the more efficient organs of the two. Upon this subject a considerable amount of interesting and extremely valuable labour has been expended, and a copious literature has accumulated, but most of it has been published through channels of very different kinds in many countries. The result is that much information of importance for the elucidation of the practical problems of to-day is only accessible with difficulty, and is frequently set out in a form in which it is difficult for investigators to appreciate. The Committee on the Physiology of Vision of the Medical Research Council has performed a real service in gathering together this scattered literature, correlating it, and presenting it in a form[1] wherein all that is of note is ready to hand for the guidance of further work. Miss Dorothy Adams, who compiled this review of the literature, is to be congratulated on the thoroughness with which she has done her work. Within the compass of 114 pages she has annotated and correlated the results of approximately 900 papers, a feat which is rendered more commendable in view of the clarity and unbiased presentation of the subject. It is admitted that the report forms somewhat difficult reading, but this is readily forgivable when one remembers the wealth of information that it contains and the difficult nature of the subject. All aspects of the question are included: perception and visual acuity; the factors causing individual variations; vision in relation to the stimulus; subjective characteristics; variations in pathological conditions; adaptation in animals; the more academic questions of the changes (structural, chemical, and electrical) which accompany the process; and the theories which from time to time have been put forward to explain it.

SCHOOL MEDICAL INSPECTION IN NEW YORK.

DR. SHIRLEY W. WYNNE, commissioner of health for New York City, recently called a meeting of the presidents of the five county medical societies to lay before them a plan providing for a complete medical examination of each child registering for school in September. He said that approximately 50,000 children enter school for the first time at the beginning of every term in September and February. In accordance with Section 200 of the sanitary code of the city every child must produce, at the time of its enrolment at school, a doctor's certificate showing that a complete examination has been made in order to discover and correct any physical defects. Dr. Wynne explained that until such time as the medical practitioners of New York showed themselves unwilling to engage actively in preventive medicine, he was opposed to the department of health expending city funds for work which the people were able and willing to have done by their family doctors. Of the children examined last February, 38 per cent. showed some form of physical defect. Of these, 25 per cent. had defective teeth, 16 per cent. had enlarged or diseased tonsils, 14 per cent. were undernourished, 13 per cent. suffered from defective nasal breathing, 10 per cent. had defective vision, over 1 per cent. had some form of heart disease, while another 1 per cent. had defective hearing, or orthopaedic or nervous defects. The commissioner's scheme includes the sending of a letter to each parent who registers a child, calling attention to the law and urging that the child should be taken to the family doctor for examination before going to school. In the case of children whose parents are too poor to pay for the services of a doctor, medical inspectors of the Health Department will make the examinations in the schools. "But I urge parents," said the commissioner after the conference, "to go to their family physicians wherever possible. We believe that the family doctor is the one to perform this medical examination." A special effort will also be made to see that all children who enter school for the first time are immunized against diphtheria.

INFECTIOUS DISEASE AND MENTAL BREAKDOWN.

THE relationship of acute infectious diseases to mental disorder is again discussed in the annual report of the chief medical officer of the City of Birmingham Mental Hospital. Dr. T. C. Graves drew attention last year to the association of influenza with the onset of mental disorder, and distinguished two main divisions of cases—an "immediate" and a "delayed" group. In the former the onset of mental trouble was closely related to the attack of influenza; in the latter the relationship was less obvious, and some time had elapsed between the occurrence of the influenzal attack and the development of mental symptoms, during which interval the patient was fairly well and even able to work, or perhaps was experiencing vague and indefinite symptoms without being

acutely ill bodily or mentally. In his present report, which deals with the year 1928, he adds further corroboration of his previous findings. The recent severe epidemic of influenza was responsible for many immediate cases, especially amongst persons of advanced years, in whom delirium and severe cardio-vascular intoxication were the prominent features. Among the "delayed" cases, careful examination of the case histories, coupled with the findings on investigation, left little room for doubt that, even when patients appeared to have been relatively well in the interval, a connexion did exist between the influenzal infection and the mental breakdown. In these "delayed" cases, in Dr Graves's opinion, areas of unresolved infection persist after the acute infective process has subsided, and develop their own peculiar activities after a period of apparent latency. It is interesting to note that Dr. Graves has also collected a group of cases in which septic disease processes could be traced back to other types of acute infective processes, such as scarlet fever, measles, and pneumococcal and other infections. He expresses the hope, therefore, that the new serotherapy for scarlet fever may be a possible preventive of mental disorder in later life. In this connexion he refers to the observation of Sir William Gowers that epilepsy may be a sequel of scarlet fever, measles, and typhoid fever in that order of frequency, and that more cases were consecutive to scarlet fever (apart from the influence of nephritis) than to all the other acute diseases put together.

THE INTERNATIONAL CONFERENCE ON TUBERCULOSIS IN ROME.

THE somewhat belated report of the sixth conference of the International Union against Tuberculosis,[1] held in Rome in September, 1928, was published in August. Three main questions were debated: the first, a biological one, was concerned with the filterable elements of the tuberculous virus, and the discussion was opened by Professor Calmette of Paris. The second question was clinical—the diagnosis of infantile tuberculosis. The social question dealt with the organization of antituberculosis measures in rural districts. The opening paper in this section was delivered by Dr. William Brand of London. Further discussions ensued on Carlo Forlanini and artificial pneumothorax, on the surgical treatment of pulmonary tuberculosis, and on compulsory insurance against tuberculosis in Italy. Signor Mussolini, under a law of October, 1927, is in process of collecting a fund of 300 million lire per annum, by means of a compulsory insurance contribution of 35 lire per head, towards an antituberculosis compaign. The fund is to be controlled by the National Social Insurance Office, which will house patients in hospitals and post-sanatorium establishments. It is not clear from the address of the Hon. Alessandro Martelli, Minister of National Economy, whether the patients are to be retained in the post-sanatorium establishments for the rest of their days, but he does remark that "the poorer classes are unfortunately prejudiced in these matters," and "it will be necessary to create a new spirit in these circles." It would appear that Professor Brauer of Hamburg did not submit his conclusions on the surgical treatment of pulmonary tuberculosis to an expert in the English tongue; hence the cryptic sentence: "for the indication and investigation of collapsion therapy is the cognizance of the lung-volumina of the patient of great importance." The papers are conveniently reproduced in the report in three languages—English, French, and Italian. The discussions were carried on by representatives of cities as wide apart as Saranac Lake and Tokio. Sixteen English representatives were present at the conference, but, excepting Dr. William Brand, the only one recorded as speaking was Sir Robert Philip, who briefly affirmed his view that "the correct interpretation of tuberculous infection in childhood afforded the key to the ultimate eradication of tuberculosis."

DANGEROUS DRUGS ACTS.

WE have received from the Home Secretary an intimation that by Order in Council made under Section 8 (2) of the Dangerous Drugs Act, 1920, Part III of that Act—which provides for the control of morphine, heroin, and cocaine—has been applied to the esters of morphine, their respective salts, and to any preparation, admixture, and extract containing them. The effect of the Order is that these drugs may not be imported into or exported from the United Kingdom and Northern Ireland without a licence issued by the Secretary of State under the Dangerous Drugs Act; as regards internal control, the Consolidated Dangerous Drugs Regulations, 1928, apply to them. With the exception of diacetylmorphine (heroin), however, the esters of morphine are not manufactured, nor, as far as is known, are they to be found in commerce in this country. They form a group of the derivatives of morphine which have, if improperly used, ill effects similar to those of morphine and from which morphine can be regenerated. There is no recognized use at present of the esters of morphine (with the exception of diacetylmorphine) in medicine, and until recently there was no manufacture of them; but it has been discovered that illicit traffickers on the Continent have had recourse to these compounds for the purpose of evading the restrictions of the International Conventions and the national laws based on the Conventions, and that large quantities of the esters were being manufactured in some countries. For this purpose the League of Nations has therefore recommended the inclusion of the esters of morphine among the drugs to which the International Opium Convention applies, and in accordance with this recommendation the provisions of the Dangerous Drugs Act have been extended to them. The esters of morphine do not include and should not be confused with the ethers of morphine—for example, methylmorphine (codeine), ethylmorphine (dionin)—to which the Dangerous Drugs Acts do not apply.

LIEUT.-GENERAL H. B. FAWCUS, C.B., C.M.G., D.S.O., K.H.P., has been appointed Director-General, Army Medical Services, War Office.

THE report of the departmental committee of the Ministry of Health on the training and employment of midwives was issued on Tuesday evening, September 17th. Sir Robert Bolam was chairman of this committee, and it was instructed to consider the working of the Midwives Acts, 1902 to 1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery), and the conditions under which midwives are employed. We propose to make further reference to this report in a later issue.

IT will be recalled (*British Medical Journal*, March 23rd, p. 562) that the Medical Research Council, in its report for 1927-28, called attention to the results of certain investigations which had been conducted by Dr. Dora Colebrook on the physiological and therapeutic effects attributed to ultra-violet light. A full account of these investigations, which included experimental studies on ultra-violet irradiation of school children and irradiation treatment of varicose ulcers, has now been published by H.M. Stationery Office in the Medical Research Council's Special Report Series. A detailed notice of this report will be published next week.

Nova et Vetera.

DR. JOHN MOORE, 1730–1802.

WE were recently shown a print of an etching with a rather curious history. It was taken from a plate which was reported to have been dug up in the neighbourhood of London, and had then been cleaned up and freed from certain blemishes by Mr. W. M. Harris of Kendal. The subject represented is the head of a man of middle age with bushy eyebrows and an aquiline nose. The plate is inscribed "John Moore, M.D.," but bears no name of an artist, only "Published as the Act directs Nov. 24, 1804."

The library of the Royal Society of Medicine possesses a copy of the same etching, also without the artist's name, as well as four other prints from portraits of Dr. John Moore. In the Print Room of the British Museum there are five prints; among these the anonymous etching is not to be found. These five prints are after portraits by George Dance, R.A., the original drawing of which is in the National Portrait Gallery, by Samuel Drummond, A.R.A., Sir Thomas Lawrence, P.R.A., Gavin Hamilton, and "Cochrane of Rome." Besides these there is in the British Museum library a stipple engraving as frontispiece to "Mooriana," "Engraved by Hopwood from an original Drawing," which latter, according to the *Dictionary of National Biography*, is by W. Lock. There is a copy of the anonymous etching in the library of the Royal College of Surgeons of England.

DR. JOHN MOORE.

A person of whom no fewer than seven portraits are extant must have been of considerable note in his day, and one naturally asks how it was that he became so well known. The *Dictionary of National Biography* and librarians and students of literature tell us that he was the author of *Zeluco*, a novel which had a great vogue in its day, and forms volumes xxxiv and xxxv of Mrs. Barbauld's British Novelists. He was also the father of Lieut.-General Sir John Moore, the reformer of the training of the British infantry, who fell in the hour of victory at Corunna in 1809.

John Moore, like many another successful person, was the son of a minister. He was born at Stirling in 1730. He studied at Glasgow University, and at the age of 17 received a warrant as surgeon's mate in the army, and served in Flanders. As is well known, at this time it was customary to license young men after a short apprenticeship and an easy examination to serve in the navy and army as surgeons' mates. Those so licensed who afterwards returned to civil life often sought no other qualification. Not so John Moore; leaving the army on the conclusion of peace, he studied in London and Paris, at which latter place he was patronized by the British Ambassador, the Duke of Albemarle, and appointed surgeon to his household. On returning to Scotland he was for some years engaged in practice, and obtained the degree of Doctor of Physic of Glasgow University. When about 40 years of age the whole bent of his future activities was determined by his introduction to the family of the Duchess of Hamilton. Her elder son, the seventh duke, died of consumption at the age of 15 under Moore's care, and he was entrusted with the care of the next son—who succeeded to the title—on a five years' Continental tour. Two books were the outcome of this tour: *A View of Society and Manners in France, Switzerland, and Germany*, published in 1779, and *A View of Society and Manners in Italy*, published in 1787. Each work was in two volumes. To them succeeded in 1789 Moore's most famous but now unread book, *Zeluco: Various Views of Human Nature taken from Life and Manners, Foreign and Domestic*. The travels are still readable, for they contain shrewd observations on places and people, and include interviews with Voltaire and Frederick the Great; but the novel can only be called stilted and dull. It deals with the life of a thoroughly bad young man who ends by dying in agony from a penetrating wound of the abdomen. The humour in it falls flat on the modern reader, and the tragedy is melodramatic. Yet in the first quarter of the last century it was very popular. Mrs. Barbauld described it as "one of the most entertaining we possess, from the real knowledge of the world which it displays and the humour and spirit of the dialogue," and Byron is said to have meant to model *Childe Harold* on its hero. Moore went to France again with another invalid, Lord Lauderdale, in 1792, and was in Paris at the time of the taking of the Tuileries and the September massacres, of some of which doings he was an eye-witness. On his return to England he published a most interesting account of this visit and tour in a journal in two volumes, which was quoted by Carlyle.

As the evidence of one who was on the spot, if not an actual eye-witness, of all the tragic events of those months, this journal is still of interest. In 1797 he published a memoir of his friend and patient, Smollett. His other works, including a popular one called *Medical Sketches*, are none of them of interest. He died in 1802, and a year later selections from his various works were edited by the Rev. F. Prevost and F. Blagdon, Esq., as "Mooriana" in two duodecimo volumes, with a frontispiece portrait already mentioned. His works, in seven volumes, with a memoir by Robert Anderson, were published in 1820, with a frontispiece portrait from the painting by Gavin Hamilton.

It is evident that Dr. John Moore was a person of very widespread fame in the England and Scotland of his day, and his reputation endured for a considerable time after his death. Yet nowadays his famous novel is only remembered by students of the history of British fiction, and his name is more likely to survive as that of the subject of the brush and pencil of Lawrence, Dance, and Drummond than as that of a popular author, or even as the father of the creator of the British light infantry.

MUIRHEAD LITTLE.

RADIUM TREATMENT OF MALIGNANT AND NON-MALIGNANT DISEASES.

A NEW ZEALAND REPORT.

A DIFFICULTY in assessing the relative value of surgery and irradiation in the treatment of uterine cancer has lain in the fact that the cases subjected to the two forms of treatment have not been strictly comparable in type. An unduly favourable impression of the value of a treatment may be obtained by confining its application to specially selected cases; a treatment may be unjustly condemned if those who apply it are obliged to take indiscriminately whatever cases they can get. Special interest, therefore, attaches itself to the results obtained in the radium and deep therapy department of Christchurch Hospital, New Zealand, where no selection of cases was made and where radium treatment was given to patients whose disease was in an advanced, inoperable state, and for whom the most that could be hoped was the relief of pain.

Dr. P. Clennell Fenwick, the officer in charge of the department, in his report[1] for the year ending March 31st, 1929, states that of 48 patients treated between 1925 and 1929, 26 were alive at the end of the period covered by the report. The patients who died survived irradiation for periods varying from three to thirty months. Of those alive, one patient reported "well" forty-one months after treatment; 18 were well at the end of periods varying from three to forty months; 1 was ill at the end of thirty months; 1 in "poor health" at the end of twenty-four months, and 1 at the end of ten months; 4 cases were too recent to report.

Cancer of the Uterine Body.

Of 10 patients treated with radium between 1924 and 1928 for cancer of the uterine body recurring after operation 5 are still alive, 2 have survived fifty-three months, 2 for thirty six months, and 1 for thirteen months. During the period 1925 to 1928 6 patients suffering from this condition were subjected to operative treatment, preceded, however, by irradiation; all of them are alive to-day, the period since treatment varying from five to forty-eight months. Of 5 patients treated with radium only, 3 are alive to-day—one after thirty-three months, one after twelve months, and one after seven months. Dr. Fenwick, in the treatment of cases of uterine cancer, strongly recommends, in addition to the use of radium, the application of a full course of deep x rays; this, he believes, may be effective in destroying any wandering cancer cells.

Treatment of Menorrhagia.

Radium has proved to be remarkably effective in the treatment of patients suffering from menorrhagia. *Fifty milligrams* of radium element enclosed in a platinum tube of 1 mm. wall thickness and surrounded by rubber tubing 1 mm. thick, is applied for twenty-four hours to the interior of the uterus. Every care is taken to exclude the presence of malignant disease or fibroid tumour. Of 84 patients thus treated since 1924, 73 are free from bleeding, 2 have been lost sight of, 8 are too recent to report on, and 1 was found to have a submucous fibroid tumour, which was later treated by operation. In the majority of cases the bleeding disappeared at once; the longest interval between treatment and amelioration of symptoms was seven months. Of 20 patients who had pain before treatment, 15 reported complete relief, 4 partial relief, and 1 no improvement. In a letter which he contributed to our columns on March 9th (p. 473), Dr. Fenwick expressed the view that the extraordinary success of radium treatment in the uterine haemorrhage of middle life was due to the action of the gamma rays upon the ovarian tissue, causing a practical spaying. Inquiry into their after-history showed that all the patients treated experienced hot flushes, sweating, headaches, and other menopausal symptoms. In the report under review he is able to state that he could find no evidence that the radium-induced climacteric differs in any way from the normal, except, of course, in its rapidity.

Treatment of Uterine Fibroids.

The use of radium in the treatment of fibroid tumours of the uterus was restricted to cases in which the patient was physically unable to undergo operation or definitely refused it. In each case the dosage was 50 milligrams of radium element applied to the interior of the uterus for twenty-four hours. Six cases have been treated; in 2 the haemorrhage has ceased and the patients are in good health; 1 patient, after reporting herself in good health, has been lost sight of; in 1 patient a uterine tumour which reached to within one fingerbreadth of the umbilicus disappeared in six months, and 2 cases have been treated too recently to report on.

Carcinoma of the Breast.

Two cases of inoperable carcinoma of the breast, treated with radium only, were apparently well at the end of the period covered by the report, six months after the treatment. Of 10 cases in which cancer of the breast recurring after operation was treated with radium 3 died, 2 were alive but very ill, and 5 were lost sight of. During the period 1924 to 1929, 14 cases were treated with prophylactic doses of x rays after the operation; only 1 of these is dead, the remainder having survived for periods varying from three to fifty-four months since the operation. It is, says Dr. Fenwick, impossible for any surgeon to know whether the scope of his operation has been wide enough to include every focus of disease, and the x rays are applied in the hope of destroying any cancer cells that may have escaped removal. Patients with carcinomatous ulceration of the chest wall have been relieved by the application of soft x rays.

Growths of the Mouth and Larynx.

During the period 1924 to 1929, 88 patients have been treated for ulceration and growths on the lip. Pathological examinations were not carried out, Dr. Fenwick holding that removal of portions of tissue for section may hasten the spread of the disease to the submaxillary glands. The cases, however, had every symptom of malignancy, and he classifies them as clinical, not positive, cancer. No case was treated that had signs of glands under the chin. Treatment has been carried out by applying flat plaques of radium inside and outside the lip, to obtain cross-fire into the growth, and by placing a heavy radium pack under the chin to act prophylactically on the submaxillary region. All actual growths were treated with buried needles. Of the cases treated, 49 were discharged free of symptoms, 34 have been lost sight of, and 5 are still under treatment.

The only cases of cancer of the larynx sent to the department were those in which glands in the neck had already appeared; these cases were treated with deep therapy, and although no cure has been obtained progress of the disease has been temporarily arrested. One case of papillomata of the larynx in a young boy was treated by placing a 50-milligram tube in the middle of the growths by way of a tracheotomy opening. After seven applications of two hours each the papillomata on the right side of the larynx disappeared and those on the left side were seen to be diminishing.

Cancer of the Skin.

Considerable success has been obtained in the radium treatment of rodent ulcer. In every case in which there has been reasonable doubt as to the diagnosis Dr. Fenwick, though greatly averse to the proceeding, has taken a section for pathological report. He believes that when the ulcer is close to the eye there is danger of opening vascular channels and permitting the escape of cancer cells, and prefers to base his diagnosis on the history, absence of pain, absence of smell, absence of glandular enlargement, and the appearance of the ulcer when all crust has been cleaned away with benzine. So far radium has been applied to 117 cases, none of which had previously been subjected to surgical or any other form of treatment; 112 of these were discharged with no trace of ulceration. Of 5 patients in whom the condition recurred, 3 were healed by further treatment, 1 died, and 1 was transferred to a surgeon for wide excision of the ulcerated area. Special difficulty is found in the treatment of rodent ulcer recurring after previous treatment by surgery, caustics, x rays, or snow. According to Dr. Fenwick, such treatment destroys the trophic nerve supply to the ulcerated area, and causes the tissues to lose their radium-sensitiveness. Of 36 such cases treated with radium, 31 appear to have been cured; one of the patients died in a sanatorium, one died with metastasis, and three were finally subjected to surgical treatment. The average number of radium applications required was three, but some patients needed more than three.

Epitheliomata of the skin present therapeutic problems entirely different from those of rodent ulcer. A specimen for section is taken whenever possible; to deal with the almost certain involvement of the neighbouring glands treatment is applied not only to the growth, but to the area supplied by its lymphatics. The department has found the only effective treatment to be the burial of needles containing 5 or 10 mg. of radium element in the substance and around the margin of the growth; 40 cases were treated during the year under review, and all reacted satisfactorily. It is as yet too early to report on end-results.

Radium has proved a highly effective remedy for naevi and angiomata. The best and quickest results are obtained in young patients, 103 out of 115 treated being symptom-free. Two adults have been treated, but without improvement.

[1] Annual Report of the Radium and Deep Therapy Department, Christchurch Hospital, New Zealand, 1928-29.

India.

Ophthalmic Treatment in Madras.

HOSPITAL reports, especially those which are concerned mainly with statistics, can be very dreary reading, and it is therefore with great pleasure that attention is directed to the annual report for 1928 of the Government Ophthalmic Hospital in Madras. The medical superintendent, Lieut.-Colonel R. E. Wright, C.I.E., I.M.S., has taken full advantage of his opportunity to provide a really interesting critical account of the operative and therapeutic procedures which he employs, and his statistics indicate that the experience on which his opinions are based is very considerable. After a timely tilt against those who, with but little knowledge or even genuine interest, propound dogmatically their views on cataract extraction as though this was the only important ophthalmic condition in India, he proceeds to discuss the changes which have been gradually made in the technique of cataract extraction in the Madras Hospital during the last ten years; the chief of these relate to methods of controlling the patient and eyeball at the time of operation and subsequently, and of dealing with immature cataract. Nearly all the patients in that institution are subjected to novocain blocking of the seventh nerve, or the ciliary ganglion, or the circumorbital muscles, or by local infiltration of the levators. Control after the operation is effected at present by suture, but Colonel Wright anticipates that some more simple device will eventually be found practicable. Where individual nursing is not available in the post-operative stages, the quieting of very restless patients is effected by drugs. Although a few years ago Colonel Kirkpatrick had suggested the use of bridge flaps, the procedure was not adopted in the Madras Hospital until early in 1928, in view of the difficulty in controlling globe movements and the exceptional liability of the patients to conjunctival haemorrhage. Although it is admitted that a bridge flap is not so efficient as suturing or clipping, still it affords a quick method of maintaining the edges of the wound in apposition, and thus reduces post-operative complications. Various kinds of bridge flaps have been tried; the formation of a central button-hole has now been given up in view of the loss of time involved. It is not so much the actual cutting of the bridge which takes the time as the delivery of the lens afterwards; this must of necessity be more slowly and carefully undertaken than when a cornéo-scleral section or simple flap operation has been performed. The cortical matter, moreover, does not come away so cleanly; although mixed with blood-clot, it can be efficiently dealt with by the irrigator. South Indian hospital patients are more liable to bleed when the sclera or conjunctiva is cut than is the case with patients elsewhere; Colonel Wright attributes this to the vascular degeneration to which the bulk of elderly patients in Madras appear to be subject. Many of them, indeed, show a vascular state which may be included under the term "arterio-sclerosis decrescens." Moreover, they do not react so well to adrenaline as do European patients. The iridectomy adopted is nearly always of the peripheral button-hole type. The vitreous loss rate for all types of cataract and all operators is low—namely, 1.87 per cent., and for a straightforward capsulotomy 0.75 per cent. The iris prolapse rate has considerably diminished; this is attributed to the use of a bridge flap. For all operators and all cataracts the figure was 1.39 per cent.; for straightforward capsulotomy 1.16 per cent. During the year under review a clinical investigation of most of the primary glaucoma cases was instituted, and has been continued into 1929 with a view to testing various methods of non-operative treatment. The large number of 2,392 refraction cases was dealt with, which represents an increase over previous years. After subjective testing nearly every patient was freely examined under a mydriatic; muscle balance examinations and power tests were extensively used, as was the ophthalmometer when considered necessary. The patients were required to return for a post-mydriatic instillation. In view of the increased time now devoted to the teaching of refraction and field work, it has been decided to double the size of the refraction room so as to allow six medical practitioners to conduct the routine testing instead of three as at present. Colonel Wright's report includes also practical clinical details of a number of interesting cases, including two of angiomatosis retinae. A considerable amount of time was expended during 1928 on investigations *in connexion with an epidemic of superficial punctate* keratitis which became apparent in May and continued into the new year. Clinical teaching was given to undergraduates and post-graduates, and special training was arranged for Government medical officers, civil assistant surgeons, and others.

Small-pox in Bengal.

In his report for the year 1923 Dr. C. A. Bentley, Director of Public Health for the Province of Bengal, foretold a specially severe recrudescence of small-pox which might, indeed, be expected to reach pandemic form in 1930–33. Since 1900 small-pox deaths in the province have been steadily increasing, and an epidemic which commenced in 1924 with over 10,000 cases is still continuing. The mortality has been rising regularly year by year, and now in the annual report on vaccination in Bengal for the year 1927–28 Dr. M. E. Sufi, assistant director of public health in charge of vaccination and vital statistics, states that it has already reached the figure of 39,700. The situation, therefore, calls for serious attention, and intensive campaigns of mass revaccination in every part of the province are advocated. It is thought that the present epidemic may be the forerunner of the apprehended pandemic and may subsequently merge into it. To meet the emergency a request has been submitted to the local government for adequate funds to be allotted in the public health budget for the ensuing year to enable local authorities to conduct intensive campaigns of mass revaccination under the supervision of the Public Health Department. All such local bodies have been asked to do their utmost to put the public health organization of the province on the best possible footing, and to extend vaccination and revaccination as widely as possible. Intensive campaigns have been started in various districts, and the Government staffs have been instructed in many places to help the local authorities in these activities. Dr. Sufi publishes statistics which indicate that primary vaccination without revaccination has never been able to control an epidemic of small-pox. He thinks that until quite recently the greater attention paid to it has caused the value of revaccination to be overlooked to a great extent. Arrangements are also being made for obtaining a large supply of vaccine for the threatened emergency.

Relief of Blindness in India.

In a communication which has been addressed to the Viceroy on behalf of the All-India Blind Relief Association it is estimated that there are between one and one and a half million blind persons in India. The census reports give a lower figure than this, dealing only with the totally blind, and it is not denied that large numbers of partly and completely blind persons are not included in these estimates, since they take no steps to obtain treatment and so do not come under observation. With a view to dealing with these people, blind relief associations have been formed in various places since 1919 when the first, after a brief life in the Ratnigiri district, succumbed. Others were started later on a more satisfactory footing, and the All-India Blind Relief Association was created to affiliate them and to improve and extend this form of relief. Very useful work has been performed by these local associations and the central body. Thus in Bijapur in 1918 there were seven ophthalmic operations, and 3,420 cases were treated medically; in 1920, when the All-India Association started work, there were 465 operations and 7,820 cases treated medically; in 1927 the number of operations had risen to 1,866, and in 1928 the cases treated medically to 29,000. Bijapur has an organization of trained village field workers who hunt up new patients, sending the more serious cases into hospital; they also inspect infants for the first ten days after

birth with a view to *detecting ophthalmia neonatorum*. In Sind the All-India Association has employed in the past medical officers to tour through the villages, camp at suitable spots, and conduct ophthalmic treatment. Financial difficulties have, however, hindered the work here as elsewhere, and only one of these medical officers is at present so employed. The cost of carrying on this scheme in Bijapur with a population of 800,000 was about 16,000 rupees in 1927. A grant is received from the Bombay Government, but more financial support is urgently needed here as in other places. An appeal has therefore been made by the Central Association to the Viceroy for a share in the money which will be collected in connexion with the All-India Thanksgiving Fund.

Canada.

[FROM OUR CORRESPONDENT IN MONTREAL.]

University Appointments.

DR. W. W. CHIPMAN has tendered his resignation to the board of governors of McGill University; he has been a member of the teaching staff since 1900. He was appointed professor of gynaecology in 1910, and two years later was professor of obstetrics and gynaecology. His professional attainments are well known, and his brilliant qualities in teaching fully realized in his own university, where his retirement will be keenly felt. His successor has not yet been appointed. The position of professor of surgery in the Faculty of Medicine of the University of Toronto, which became vacant on the death of the late Dr. C. L. Starr last December, has been filled by the appointment of Dr. W. E. Gallie. Dr. Gallie's influence on the progress of orthopaedic surgery has been long recognized. He delivered the Hunterian Oration in 1924, under the title of "The transplantation of the fibrous tissues in the repair of anatomical defects."

Dalhousie University.

The Dalhousie Medical School in Halifax has this year celebrated the sixtieth anniversary of its founding. The occasion was marked by important functions and by the issue of a special issue of the *Nova Scotia Medical Bulletin*, containing much interesting and valuable historical material in connexion with the teaching of medicine in Eastern Canada. Coincident with this anniversary was the seventy-fifth annual meeting of the Medical Society of Nova Scotia, which retains a vigour that shows no sign of declining. The medical school is a later development of a university which was founded one hundred and ten years ago with the aid of customs money collected by Great Britain in the State of Massachusetts during the war of 1812, a fact which was referred to by the Hon. William Phillips, United States Minister to Canada, on the occasion of his receiving the LL.D. at Dalhousie this year.

Practitioners and Public Health Associations.

It is inevitable that the general practitioner should find grievances from time to time in the overlapping of the activities of various public health associations and his own work. The Toronto Academy of Medicine has formed a committee to deal with complaints and difficulties of this nature, and a good deal of very useful work has been done. Complaints by private practitioners regarding the activities of the Department of Public Health have been taken up, and in most cases satisfactorily disposed of. Particularly in the matter of the care of the pre-school child by various welfare councils, care is being taken to see that the rights of the general practitioner are not infringed. On the other hand, it is being pointed out to the practitioner that a certain degree of co-operation with these bodies is necessary. In the Western Provinces, however, particularly in Alberta, there is still a good deal of the action of the Provincial Govern- municipal travelling clinics, and, more in salaried practitioners to work in the sparsely settled outlying districts. Three women doctors have lately arrived from Great Britain under this scheme, the Government being responsible for their salaries, the district for housing accommodation, and the family of the patient for local transportation. The Government states that it must provide for the medical needs of these far-flung regions, but medical practitioners assert that the reason for the falling-off of the number of men who take up country practice is the continued interference of the Government with their opportunities of obtaining an adequate income. Some see the shadow of State medicine in the situation, others recognize that there are regions in which the medical attention available is very scanty—it may even be non-existent—and something must be done to meet the deficiency. Even those who realize that great spaces have to be reckoned with are impressed when they actually travel through the West and meet the men who are carrying on the work of general practice. Even to attend the medical society meetings, which are becoming so keenly supported, largely as a result of the travelling lecture teams sent out by the Canadian Medical Association, men will often motor fifty or sixty miles. At one of these meetings recently I met men who had come ninety and seventy miles respectively.

Chiropractors in Alberta.

The chiropractors in Alberta are trying to remove the restrictions imposed on them by the Chiropractic Act. This Act requires that all applicants should pass an examination in the basic subjects, the examining board to be composed of two chiropractors, two doctors from the staff of the Alberta University, and a layman to act as chairman. Up to the present no one has passed the examinations.

England and Wales.

Health Measures in Birmingham.

THE complexity of modern civilization is particularly obvious in the larger cities, and, consequently, the preservation in good health of the great aggregations of population in such communities can be no simple matter. Direct attacks on disease have to be associated with the direct promotion of health, but the value of indirect attacks on disease must not be overlooked, and this is one of the main contentions in the annual report for 1928 of the medical officer of health for the city of Birmingham. Dr. H. P. Newsholme calls attention in the maternity and child welfare section of his report to the deaths from pneumonia in children under the age of 5. It is shown that these occurred mainly in the poorer houses, and that the children picked out by the disease were those subject to recurrent catarrh in families where the parents in an unusually high proportion showed conditions of chronic ill health. Dr. Newsholme emphasizes the significance of the implication that an indirect attack on the disease may be effective in that the improvement, on the one hand, of the environmental conditions implied in the alterations to housing, to general sanitation, and to scavenging, and the improvement, on the other hand, of the personal health of the child under the child welfare scheme, and of the parent under the national health insurance scheme, will remove conditions which at present encourage the prevalence of the disease. These conclusions followed a careful inquiry, under medical direction, which was made into 255 cases of death from pneumonia in these children. The largest age group of cases was that comprising infants between 6 and 12 months old (31 per cent.); the next highest was the group of children between the ages of 1 and 2 years (25 per cent.); and the third the group aged from 1 to 6 months (21 per cent.). The increased resistance to pulmonary tuberculosis as the child began to grow up was shown by the fact that, in the group of children between 2 and 5 years old the mortality from pneumonia was only 15 per cent., so that it is clear that the most dangerous age period for pneumonia is from 1 to 14 months. The increasing percentage of ailing children among the older groups with a high percentage for recurring pneumonia and bronchitis appears to emphasize the probability of infection at a very early age, and its continuance with quiescent

periods until a fatal attack supervenes or the child is restored to health. Dr. Newsholme comments on the importance in this connexion of defective diet, which was discovered in a high percentage of the cases; he also urges the provision of better facilities for convalescence. The population of Birmingham is nearly a million, but the death rate—10.9 per 1,000—is lower than the average (11.7) for England and Wales. Pulmonary tuberculosis was the greatest cause of death between the ages of 20 and 25, after which the mortality from heart disease assumed a marked predominance, though cancer played a large part. Respiratory diseases generally, and diseases of the nervous system, became of increasing importance with advancing years. Dr. Newsholme therefore discusses the problem of atmospheric pollution. He states that Birmingham is a city with over 1,100 factory chimneys, about one-third of these being connected with metallurgical furnaces. From ten to thirty-five tons of sooty deposit fall monthly in different areas of the city per square mile, and these figures indicate that a considerable reduction in the amount of soot in the atmosphere can yet be made. The number of canal boats registered at Birmingham is steadily increasing, and it is found that canal-boat life is very good for the health, though it has the disadvantage of interfering with the education of children. The canal-boat people are characterized as being well nourished, hardy, and self-respecting. Dr. Newsholme illustrates by graphs the satisfactory progressive diminution in the annual death rate from tuberculosis, the figure of 150 in 1901 having fallen to about 80 in 1928. Ophthalmia neonatorum is on the increase in the city, for reasons which are not at present obvious. The training course for health visitors opened jointly by the University of Birmingham and the Public Health Committee in the autumn of 1927 was established on a more permanent basis early in 1928, and has proved most successful in promoting the supply of properly trained health visitors, both for Birmingham and for neighbouring areas taking part in the scheme. By-laws for houses let in lodgings have also been redrafted in order to increase the powers for dealing with this very difficult and generally unsatisfactory class of dwelling; the revised by-laws did not come into effect during the year under review. Child welfare centres are increasing in number, and it is hoped that more will soon be obtained.

Post-Graduate Teaching in Manchester.

As in previous years, post-graduate lectures and demonstrations on medical and surgical subjects will be given at the Manchester Royal Infirmary during the winter and spring sessions, on Tuesday afternoons at 4.15. The course will be opened on September 24th by Mr. J. P. Buckley, who will discuss some points relating to the etiology and treatment of appendicitis. On October 1st Mr. F. C. Wrigley will lecture on acute suppurative otitis media, and on the following Tuesday Mr. H. H. Rayner will deal with the position of surgery in the treatment of gastro-duodenal ulceration. Lectures on special subjects will be given on Fridays, beginning on September 27th, when Dr. Catherine Chisholm will discuss the treatment and development of the premature and immature infant. On the following Friday Dr. R. Prosser White will speak on some problems in occupational dermatitis, and on October 11th Mr. C. W. W. Surridge, the city coroner, will consider the relation of the medical profession with coroners. These lectures on Tuesdays and Fridays will continue into December, and there will be a resumption of the Tuesday series next March. On Wednesday, November 27th, Dr. Comyns Berkeley will deliver the Lloyd Roberts Lecture at St. Mary's Hospital, Whitworth Street, W.; his subject will be the teaching of obstetrics and gynaecology. Further information about these courses may be obtained from Dr. E. Bosdin Leech, the Royal Infirmary, Manchester. A series of post-graduate lectures and demonstrations will also be given at Ancoats Hospital during the Michaelmas term, on Thursday afternoons at 4.15. Dr. W. J. S. Reid will open the course on October 17th with a lecture on the haemorrhagic diathesis, and will deal with pernicious anaemia on the following Thursday. Dr. Arnold Renshaw will discuss the significance of the cytological changes in the blood on October 31st, and Professor J. B. S. Stopford will speak on spinal tumours on November 7th. Other lectures and demonstrations will follow in November and December. On each Thursday during the Lent term a "post-graduate day" of clinical teaching will be arranged by the honorary staff of Ancoats Hospital as a part of the post-graduate scheme of the University of Manchester. The programme will be posted in the medical school and in the entrance hall of the hospital a week in advance. Particulars of the special courses in connexion with the University scheme are to be found in the University post-graduate syllabus. Inquiries may be addressed to Mr. Harry Platt, M.S., F.R.C.S., 26, John Street, Manchester. All these lectures and demonstrations at the Royal Infirmary and Ancoats Hospital are free to medical graduates and senior students; announcements of each in turn will be inserted in the "Diary" of the *British Medical Journal* in the issue of the preceding week.

Research in Dairying.

The National Institute for Research in Dairying, associated with the University of Reading, was founded by the Board of Agriculture as part of the scheme of research formulated under the Development and Road Improvement Fund Act of 1909. In its report for the year 1928 attention is drawn to the fact that the number of producers and distributors of graded milk has increased, and that dairymen are gradually adopting the method of payment for milk according to its standard of cleanliness. According to the report all the official samples of Grade A (tuberculin-tested milk) sent to London by one group of farmers were found to be within the standard on delivery to the consumer at every examination made during 1928. A similar gratifying report was presented by the medical officer of health for Cardiff, and the Institute claims that these facts demonstrate the progress that is resulting from the organized study of the problems of the milk industry which has been conducted during the past fifteen or sixteen years. The experiments on the nitrogenous manuring of pasture land, which were begun by the Institute in 1925, are being continued, and have demonstrated the influence of nitrogenous manure on the number of days upon which it is possible to graze the cows and upon the amount of the milk yield. The study of different methods of butter-fat testing appears to show "that sampling and testing at each visit of the milk recorder, associated with weighing of the milk yield at each milking to ensure that representative yields are sampled, and a method of calculating the average which takes into account the variation in yield and fat at each milking and as the lactation period advances, gives an average fat percentage of definite reliability in the great majority of instances." The report of the chemical department deals with the influence of calcium in the soil, upon its content in some plants, and the possible relation of its amount in the food to the incidence of milk fever. Other work done on calcium has included a study of its effect upon cheese making and the possible influence of heating milk in altering the ratio of diffusible and indiffusible calcium. On behalf of the Empire Marketing Board an investigation has been made of fishiness in butter, which has been shown to be probably due to the same cause as oiliness in milk—namely, the presence of traces of copper. The bacteriological department has studied various faults in the industry—for example, coco-nut flavour and red spot in cheese; it is thought that the results of these studies are likely to be of far-reaching importance. Further interesting investigations have concerned the various factors which influence the presence or absence of "blueing" in Stilton cheese, and the variations in the ripening of cheese which may be found to occur when it is prepared either from clean milk or from ordinary milk. In order that the work of the Institute may develop further the staff believes that a physiologist should be appointed to study the problems of milk secretion and the effects of the constitution of milk upon its food value and upon the making of dairy products. Further, the need is emphasized of obtaining increased accommodation on the farm, additional buildings, and a more numerous staff, in order that large-scale experiments in dairying may be undertaken. These developments necessarily involve increased expenditure, and in view of

the fact that there is little prospect of assistance from Government sources the committee holds that steps should be taken to create an endowment fund which will lighten the financial difficulties from which the Institute must continue to suffer so long as conditions remain as they are at present.

Ireland.

Rockefeller Foundation Fellowships in Dublin.

In 1928 the trustees of the Rockefeller Foundation sanctioned a scheme for the establishment of three research fellowships in connexion with the School of Physic, Trinity College, Dublin. In accordance with the details of the scheme a fellowship in bacteriology and public health became vacant on October 1st, 1928, and the appointment was filled on that date. Another fellowship in biochemistry commences on October 1st next, and has now been filled by the appointment by the Board of Trinity College, Dublin, of Dr. Arthur Geoffrey Thompson, who had a brilliant career as an undergraduate in Trinity College Medical School. His distinctions include a first-class moderatorship in natural science, the FitzPatrick medical scholarship, the John Malleb Purser medal in anatomy and physiology, and a medical travelling prize. Immediately after qualification Dr. Thompson was appointed pathologist to Jervis Street Hospital. The duties of the fellowship to which he has now been appointed include the teaching of clinical biochemistry in the Medical School of the University of Dublin, as well as the prosecution of research work in that subject.

Salaries of Medical Officers in County Mayo.

At a recent meeting of the Mayo Board of Health, Drs. Moran, Ryan, O'Boyle, and McNulty attended in connexion with the suggested increase of the dispensary doctors' salaries. The secretary read a letter from the Local Government Department acknowledging receipt of the Board's letter of June 8th, from which the Minister observed that the Board agreed to adopt the scale of salaries suggested by him. The letter pointed out that the medical inspection of school children called for a highly specialized knowledge and experience, and it was essential for the observance of uniformity and proper co-ordination of arrangements that standard methods of inspection and remedy should be applied throughout the country. While the Minister was satisfied that the functions of the school medical officer could not be efficiently discharged by the dispensary medical officers, he recognized that when the public services of the country were fully organized the scope of their duties would be increased to some extent, and he was accordingly prepared to approve the dispensary medical officers being paid in accordance with the scale of salaries which was before the Board on June 8th. The letter of the Mayo Board of Health referred to by the Department for Local Government and Public Health was as follows: "The Board are agreeable to adopt the scale of salaries suggested, on the understanding that the different dispensary medical officers take over the duties of school medical inspection in their respective districts. The dispensary medical officers are willing to take on those extra duties in respect of the extra remuneration which they would receive under the suggested scale. I have been directed by the Board to inquire if the school medical inspection may be legally allocated to the dispensary medical officers in the county, or if the Minister would be prepared to accord his consent to such proposal." The Health Board unanimously adhered to their former decision as defined in their letter.

Conditions of Appointment of Nurses in Hospitals.

The Minister for Local Government and Public Health (Irish Free State) instructed Dr. Boyd Barrett, a medical inspector, to report on the circumstances connected with the suspension from duty of Nurse Bridget Hynes, who was appointed nurse in the Cavan County Hospital by the Local Appointments Commissioners on June 25th. Arising out of the medical inspector's report the Minister removed the suspension of the nurse, and directed that she should resume duty. Dr. Boyd Barrett, in the course of his report, stated that the whole situation appeared to have had its origin in a misunderstanding on her arrival at the hospital, when she informed the matron that she had received no notification from the local authority. In response to a telegram received at Enniskymon, the nurse proceeded to Cavan to take up duty. In the previous month she had been instructed by the Local Appointments Commissioners that she had been recommended for the Cavan Hospital, but it was added that as the appointment was a matter for the local authority no action should be taken until after she had been invited to take up the appointment. On arrival at the hospital the nurse stated to the matron that she had received no notification from the Board of Health (the wire received being signed "Surgical Hospital, Cavan"). In making this statement she was not only justified, but was acting according to written instructions. It appears that the matron was annoyed by a new nurse seeking official confirmation of her order. The nurse was then told that she might see the secretary of the Board of Health if she wished, and that she was to go on night duty at once. Dr. Barrett added that it was obvious that the subsequent unfortunate events were conditioned by the misunderstanding. The matron had no conception of the precise and emphatic terms of the letter of appointment; not being cognizant of these terms, the query of a new nurse apparently questioning the authority of the matron was to her objectionable. The matron had held her post for many years, and she had been accustomed to sending messages to successful candidates to fill vacancies on the staff; never before had her authority been doubted or confirmation of her instructions sought. On the other hand, the nurse, in this instance, was entirely justified in asking for notification from the local authority; she had, in fact, travelled some hundred miles at her own risk to help the hospital staff. Dr. Barrett emphasized this misunderstanding, because he believed that the ill feeling thus created was a cause of much of the trouble that subsequently ensued, and it was a misunderstanding in which it was impossible to apportion any blame. It had now been cleared up, and these officers should for the future work in harmony in the interests of the sick poor. The Minister expressed the hope that the Board would, without delay, take into consideration, in consultation with the medical officer and the matron, the question of improving the condition of the nurse, both as regards accommodation and hours of freedom from duty.

Correspondence.

POST-VACCINAL ENCEPHALITIS.

SIR,—The Rolleston Committee on Vaccination, in dealing with post-vaccinal encephalitis, has demanded further time for the completion of its investigation and the analysis of the complicated data with which it is confronted. In the meantime, the Ministry of Health in its new Order (*British Medical Journal*, August 24th, p. 371) has tried to avert the calamity that would result from an outbreak of small-pox in an unvaccinated population by authorizing certain of the recommendations of the Rolleston Committee. The recommendations as to the optimum age for vaccination are founded on data which are open to criticism, but being officially accepted they will hereafter hamper action should a small-pox epidemic be threatened. The well-founded belief that effectiveness of vaccination against small-pox is proportionate to scar area has been cast aside, on the assumption that the danger from any harmful agent which may be associated with the variola vaccine proper would be diminished with a diminution in the area of implantation.

On page 152 of the Committee's report it is stated that the Government Lymph Establishment was the source of supply in 18 out of 25 cases of post-vaccinal encephalitis which occurred in this country; but it is rightly pointed out that this source of supply cannot be specially inculpated, in view of the fact that 60 per cent. of the total vaccinations are performed by public vaccinators. It is

then explained that "17 different 'series' of vaccine were used for the vaccination of these 18 cases; one 'series' was therefore used for 2 cases. Each 'series' is a product of the vaccination of a single calf with lymph derived from another animal, generally a rabbit, but occasionally a calf. In these 17 series the lymph was derived from the cutaneous vaccination of calves with rabbit stock."

Orders by the Local Government Board required that the calf used for the production of vaccine should be slaughtered, and, if it were proved unhealthy, that the lymph should not be used. These orders were in force for many years before the rabbit was included in the scheme of cultivation; in recent rulings the rabbit is not specifically mentioned, but is covered by a wider term, "animal." In the second schedule of Statutory Rules and Orders, No. 486 of 1927, Therapeutic Substances, Section (B), para. 3, it is demanded that a "thorough post-mortem examination of the carcass shall be made by a qualified expert. A complete record of each such examination should be kept." The Rolleston Committee, however, does not state in its report whether it has examined the records relating to rabbits. In view of the hypothesis that post-vaccinal encephalitis in the human subject is "fortuitous," and of the fact that rabbits may survive for a long time after their intracerebral inoculation by means of brain material from fatal cases (Report of the Committee on Vaccination, p. 193), the value of such post-mortem records would be increased if they included the number and the medical history of rabbits which died after admission and before undergoing vaccination previous and subsequent to 1902—the date when their use was officially recognized. Fortunately, all the facts at present available about neurotropic diseases of rabbits have been summarized by Dr. Tom Hare in his valuable contribution to the discussion on encephalo-myelitis of man and animals in the Section of Comparative Medicine of the Royal Society of Medicine in March of this year. These facts show that the use of rabbits for the cultivation of vaccine involves a possible risk, yet one which long experience has shown need not be taken.

Professor McIntosh, a member of the Andrewes Committee, held that the connexion between vaccine lymph and post-vaccinal encephalitis had not been definitely excluded. The Rolleston Committee has not neglected his view, but there is nothing to show that it has tried to ascertain the action of *vaccine lymph* on the nervous system. The lymph used by the Committee had presumably been modified by passage through the rabbit as well as the calf; in short, it has not experimented with true vaccine lymph, but with *leporine vaccine*. Yet the Committee appears to have felt that the hypothesis whereby the occurrence of post-vaccinal encephalitis has been attributed to the existence of some "*unknown factor*" in *persons undergoing* vaccination—just at a time when fortuitously they were incubating one or other of the neurotropic diseases—was much weakened by the findings of Professors Turnbull and McIntosh, supported by Dr. J. R. Perdrau, to the effect that histologically post-vaccinal encephalitis could be "sharply differentiated" from neurotropic diseases likely to be thus encountered. Thus, on page 193 of the report one reads that: "The results, though occasionally suggestive, have not conclusively demonstrated the presence of a virus possessing any uniform specific pathogenicity for the rabbit. It must be remembered that in work of this kind the pitfalls and consequent fallacies are numerous."

Although the occurrence of consecutive cases of encephalitis following the use of lymph from the same source has been established, and might therefore at first sight seem to locate the source of mischief, it must be remembered that further use of the same lymph in hundreds of cases has produced no ill effects. It is presumably on this account that hypotheses of "latency" and of the "unknown factor" have been evolved.

There is no need for such hypotheses. One of us has recorded experimental evidence to the effect that though vaccine lymph which has been contaminated with a harmful agent may, by a judicious selection of normal vesicles, appear to be absolutely normal after its transmission for several generations in the calf, yet in later generations one or more vesicles of the total mass may be shown to contain the harmful agent. This experimental evidence,* coupled with the fact that neurotropic diseases may occur fortuitously in individual rabbits in which the incubation period may be longer than the five days' quarantine demanded in the Statutory Order above quoted, may serve to explain the occurrence of so-called "fortuitous" post-vaccinal encephalitis in the human subject.

So far as one may judge from the records, encephalitis occurred in this country subsequent to the use of leporine lymph. The fact that true vaccine was issued by the Army Vaccine Institute from 1880 to 1910 without disturbing accidents in two million cases should suffice to show that vaccine lymph in itself can be tolerated by subjects of vaccination at all ages. Lymph issued by the Army Vaccine Institute was used not only on men in the army and navy, but also on women and children, and in each case a report was officially required. Before, therefore, Professor McIntosh's view is rejected, vaccine lymph that has never passed through the rabbit should be tested on animals in order to discover whether its use is in any way connected with post-vaccinal encephalitis. Meanwhile, we repeat our suggestion that, as a necessary preliminary to a final verdict, the issue of any form of leporine lymph, whether manufactured at home or imported from abroad, should at once be abandoned in favour of an historically proved unmixed stock of variola vaccine.—We are, etc.,

TONSILS AND ADENOIDS IN HOSPITAL PRACTICE.

SIR,—I wish to express my complete agreement with Mr. Scott Stevenson when, at Manchester, he stigmatized as "a disgrace to British surgery the fact that there is to-day one operation—the removal of tonsils and adenoids in children—in which hospital patients are treated very much worse than private patients." It is some years since the Laryngological Section of the Royal Society of Medicine drew up recommendations which the council adopted and sent to every hospital known to undertake a regular service for these operations; these recommendations were very similar to those unanimously adopted at Manchester. (See *Proc. Roy. Soc. Med.*, 1929, xiii, Section of Laryngology, p. 29.)

There is reason to believe that the mortality rate and the incidence of severe complications is definitely higher where these repeatedly recommended precautions are still neglected, and a heavy responsibility attaches to those who do not press on the authorities under whom they serve the imperative need for these precautions being observed.

It is deplorable to gather that clinics still exist where children are submitted to operation, and, within a few hours, are sent home without adequate provision for after-care, or even precautions against their immediate contact with others suffering from infectious disease.—I am, etc.,

PATRICK WATSON-WILLIAMS.

Bristol, Sept. 7th.

SIR,—I regret that Dr. Scott Stevenson (September 7th, p. 477) should look upon my letter (August 24th, p. 368) as arguing in favour of the performance of tonsil and adenoid operations in the out-patient department. The last sentence of my letter reads, "So long as the totally inadequate in-patient provision for these cases remains, there is something to be said for treating them as out-patients, if only from the preventive aspect."

The question remains, How can we obtain sufficient in-patient accommodation, and that quickly? Until now the individual insistence of the surgeon in charge that these cases should be treated as in-patients has been as a voice crying in the wilderness. In addition, as Dr. Scott Stevenson says, similar resolutions have been passed before without much effect. Might I suggest, therefore, that since Dr. Scott Stevenson moved the resolution, he should

* An exemplification, in practice, of the persistence of a harmful contamination of vaccine lymph is reported on the authority of recognized experts in the *Farmers' Bulletin* (U.S. Department of Agriculture, 1908, No. 347, p. 379).

take it a step further and, with the co-operation of the Section of Diseases of Children, he should bring the resolution to the notice of the hospital and school authorities and ask for their views on the matter? Backed by the unanimity of the Section, I feel sure it would carry considerable weight with these bodies, and something might be done about it. Left as it is, it will go the way of previous resolutions.

It is an excellent chance for the Section of Diseases of Children to put an end to the present state of affairs.—I am, etc.,

Hull, Sept. 9th. R. R. SIMPSON.

SIR,—The resolution passed by the Section of Diseases of Children at the Annual Meeting of the British Medical Association (see *Journal*, August 17th, p. 303), that children should be admitted to hospital beds for forty-eight hours after operation, is a very sound one.

At the Bolingbroke Hospital, Wandsworth Common, some twenty children have been so treated every week for over a year, and the arrangement is highly satisfactory in every way. This step was taken owing to representations made by Mr. E. A. Peters to the medical committee, and was approved by the general committee also. It is not so unpractical as it may seem, because one bed can, if necessary, serve for three such patients during the week. An allocation of ten cots or beds will thus serve for thirty patients a week.—I am, etc.,

London, W.1, Sept. 6th. H. MORTIMER WHARRY.

THE HISTORY OF CLEIDOTOMY.

SIR,—Some thirty-four years ago, at a British Medical Association Branch meeting, I read a short paper in which I recommended simple division of the clavicles as a means of facilitating delivery in certain cases of impaction of the trunk of the foetus. The paper was published in the *British Medical Journal* on April 13th, 1895 (p. 808). Seven weeks later Professor Phänomenoff of Kazan published in the *Centralblatt für Gynäkologie* (June 1st, 1895) a paper on the same subject, and gave the name "cleidotomy" to the operation. He did not mention my earlier publication, an omission to which I at once called attention in a letter published in the *British Medical Journal* of July 13th, 1895 (p. 113), in which I cited the *Centralblatt*, and stated that I had taught and practised the operation since the year 1888. A great deal has been written on this little operation without any reference to my communication in your columns. A notable exception is the valuable paper on cleidotomy by the late Dr. J. W. Ballantyne, published in the *Transactions of the Edinburgh Obstetrical Society* (vol. xxvi, p. 24, 1901). Ballantyne gave full credit to my paper, and wrote, "The contribution of Dr. H. R. Spencer marks a new departure."

A recent number of the *Zentralblatt* (No. 17, 1929) contains a paper on cleidotomy by Jankelewitsch, with a bibliography at the end of twenty-nine publications, but no reference to Ballantyne's important review. This was followed in No. 34 of the same journal (p. 2144) by a historical review of the operation by Wille as a reply to Jankelewitsch's paper. Wille mentions the name of Ballantyne in the text, but does not give the reference, and has evidently not read Ballantyne's communication; for if he had done so he would have seen my name mentioned therein, and would have avoided an error in correcting his German confrere and purporting to give the history of the operation, by attributing to Phänomenoff an operation previously devised, practised, and published by myself. There is nothing new about Phänomenoff's communication except the name cleidotomy; nor is the division of the clavicles, as a part of other destructive operations on the foetus, a modern invention, having been described in the sixth century by Actius, who had taken the operation from Philumenos, as mentioned in my address to the Obstetrical Society in 1907. Fornari[1] in 1377 published an account of the operation under the title "clavicotomia"; his operation was combined with embryotomy. Silberstein[2] in 1882 divided the clavicles after he had performed embryotomy for an impacted foetus not permitting embryulcia. His case would have been more easily treated by the second method mentioned in my paper. Von Herff,[3] who in 1897 claimed that he had performed cleidotomy before 1895, gives particulars of the operation—namely, he perforated the chest of an anencephalic child and "in the easiest way, by separating the blades, broke the upper two ribs, together with one clavicle." This was clearly no case of simple cleidotomy.

As one interested in the history of medicine, which owes so much to the genius and industry of German writers, I take this opportunity of pointing out that it suffers somewhat from the apparent reluctance—or is it tardiness?—of German authors to publish, in their extensive bibliographies, references to the work of non-German writers. Thus my contribution to the above subject does not appear in Fasbender's great History of Midwifery, published in 1906; but one might not unreasonably expect writers in the *Zentralblatt* to be acquainted with it after thirty-four years.—I am, etc.,

London, W.1, Sept. 12th. HERBERT R. SPENCER.

"ACTIVATED" FLUORESCEIN IN CANCER TREATMENT.

SIR,—Will you permit me to add a few remarks which it was intended should appear as a footnote to the article on the treatment of cancer by fluorescein activated by radiations in the *British Medical Journal* of August 10th (p. 233).

Four photographs were given showing the rapid changes which took place in a large ulcerating carcinoma of the breast when subjected to this method of treatment. The omission was the fact that the radiological work in this case was carried out by Dr. G. Vilvandré. The technique used by him varied considerably from that used by Dr. Gouldesbrough for the other cases referred to in the article, but, as the photographs show, it was eminently satisfactory for the purpose; apart from the ultimate condition of the case. Variations in technique and the limits within which the destruction of cancerous tissue is possible, can be more fully dealt with when further results are to hand. Until quite recently, bad results and good results, thought to be due to differences in the *x*-ray apparatus employed, have, no doubt, really depended upon the form of the fluorescein used.

In closing I wish to apologize to Dr. Vilvandré for the omission of his name; as I explained to him personally, the decision to include the photographs was only made two days before Dr. Copeman sailed for South Africa, and the proofs were returned without the footnote.—I am, etc.,

London, W.1, Sept. 16th. FRANK COKE.

THE RHEUMATIC TYPE.

SIR,—The article by Drs. Gray Hill and Mary Allan in the *British Medical Journal* of September 14th (p. 499) on the rheumatic type once again raises the question of whether certain types of children are more susceptible to rheumatism than others.

In spite of the fact that the rheumatic diathesis is frequently mentioned, there are widespread differences in the descriptions given by writers of the physical traits which make the diathesis recognizable. Three main examples are to be found in the textbooks, all differing from each other: (1) the child is a blond with blue eyes, delicate skin, and pink cheeks; (2) the child is a brunette, the eyes and hair are dark, the eyelashes long, the skin white, the complexion good, the sclerotics are bluish, and the teeth, especially the middle upper incisors, are massive; (3) the child is freckled and has red hair.

The first example is the description of a typical Nordic child, and the second of a Mediterranean child. The third is of a type not so commonly seen as the others, except in certain localities. The first or Nordic type is described in the textbooks of Garrod, Butler, Thursfield and Paterson, and of Bernard Myers, among others; the second, or Mediterranean type, in Robert Hutchison's volume of lectures on diseases of children; and the third, or red-headed type, is mentioned by Still.

[3] Von Herff: *Arch. f. Gynäk.*, 1897, 53, pp. 542-546.

London school children may be grouped roughly into four types: the Nordic, the Mediterranean, those that appear a mixture of the two with sometimes an Alpine element, and, finally, a small dump-heap of unclassifiable ones. Those that lie between the Nordic on the one hand and the Mediterranean on the other are for the most part fair-haired, but with brown eyes. The child with black hair and blue eyes is rare, and since only six were seen in the collection of the following figures they have not been classified. The red-headed children are also omitted as representing a special case: it may be mentioned that the majority of the latter had a rheumatic history.

Five hundred and five children of school age were seen during a period of three months as casualty patients. They had the following distribution: blue eyes and fair hair 289, brown eyes and fair hair 145, and brown eyes and dark hair 71.

Excluding the colour of hair and eyes by which they have been thus grouped, the features of the diathesis described by Robert Hutchison were present in the following percentages:

Mediterranean type	95.8 per cent.
Intermediate type	86.2 ,,
Nordic type	29.5 ,,

Again excluding eye and hair colour, the total number with the features of this diathesis present was 276 as against 227 without.

The percentage of those giving a history of any rheumatic phenomena was:

Nordic type	29.0 per cent.
Intermediate type	38.6 ,,
Mediterranean type	39.8 ,,

A similar history in connexion with Robert Hutchison's diathesis was given in the following proportion: positive histories were present in 41.7 per cent. of cases with such a diathesis, and in 22.5 per cent. of those without it.

Damp houses, as usual, figured more commonly in the history of the rheumatic cases than the others, but this environment was present in an almost equal percentage of cases in all three of the types of children, and thus does not affect the figures given.

The following conclusions may be drawn:

1. The Nordic child is less commonly affected than the intermediate or Mediterranean child.

2. The diathesis described in this letter accurately fits in with the Mediterranean child, is less commonly seen in the intermediate child, and is more commonly absent in the Nordic child. Rheumatism is more common in the first and second types than in the third.

3. Children with the traits of this diathesis are more commonly affected with rheumatic manifestations than those which do not show them.—I am, etc.,

J. C. HAWKSLEY, M.B.

London, N 19, Sept. 13th.

THE ANAEMIA OF PREGNANCY.

SIR,—In an article entitled "Indian motherhood" in the *Journal* of July 13th (p. 63), my work on the subject is quoted, and I write to advocate caution before accepting the following statements made regarding anaemia of pregnancy.

1. "If it [recovery] takes place after delivery it is complete." It is notoriously almost impossible to keep in touch with Indian patients after discharge from hospital, and they form the vast bulk of the sufferers from this disease. Improvement once begun in these women is so gratifying that one is apt to form opinions on insufficient data, no follow-up figures having yet been published to prove them.

The need for caution in this connexion is illustrated by the case of a married Anglo-Indian woman who was admitted to the Eden Hospital last October, suffering from severe anaemia of pregnancy; she gave birth to premature twins, and was profoundly ill for weeks. Her blood count on October 11th was as follows: total red cells 1,320,000 per c.mm., haemoglobin 25 per cent., total white cells 7,812 per c.mm. The differential count showed: polymorphs 45 per cent., lymphocytes 51 per cent., large lymphocytes 2 per cent., eosinophils 2 per cent. A few normoblasts, anisocytes, poikilocytes, and polychromatophils were present. No malarial parasites were seen.

I was fortunate enough to have another opportunity of obtaining a subsequent report on February 27th, 1929, on which date she had vastly improved, and said she was perfectly fit. This report was as follows: Total red cells 3,750,000 per c.mm., haemoglobin 50 per cent., total white cells 3,750 per c.mm. The differential count showed: polymorphs 50 per cent., lymphocytes 36 per cent., large lymphocytes 1 per cent., eosinophils 13 per cent. No abnormal cells were seen.

In this case, therefore, the blood had not been restored to the normal after four and a half months, although apparent recovery had occurred and the patient felt very well. She was not seen subsequently, although she was advised to come to the hospital every month for further observation.

2. "Liver treatment has caused immediate and rapid improvement." I have tried both liver treatment and blood transfusions during the past year at the Eden Hospital, but I was unable to form an accurate opinion as to their value because the patients miscarried soon after admission to hospital, as they usually do. Since rapid improvement follows after delivery (if the patient survives it) without any special treatment, it was not possible to attribute the improvement dogmatically to the liver treatment or the blood transfusion, although, presumably, they are of great assistance.—I am, etc.,

S. A. MCSWINEY, M.B., F.R.C.S.I., Major I.M.S.

Calcutta, August 1st.

CO-OPERATION BETWEEN PRIVATE PRACTITIONERS AND HOSPITALS.

SIR,—There is a very serious hiatus in the treatment of our hospital patients to which I think attention ought to be directed without delay.

When a general practitioner sends a patient with a note to the out-patient department of a hospital he practically always receives a letter in reply from the out-patient physician or surgeon. But when that same patient, having been admitted to the hospital for operation or other special treatment, is discharged, to come again under his own care, no accompanying letter is sent—except sometimes when the specialist happens to be a personal friend. This rule applies invariably to Poor Law hospitals and to all the large voluntary hospitals, so far as I know them. It is often so difficult to get information that I now always enclose a stamped envelope for reply, and, even so, I have occasionally had to apply twice.

It is perfectly obvious that this state of affairs is undesirable. Doctors should know if their patients' gall-bladders have been removed or merely drained; if they have been sent home with one kidney or two; or what other possible surgical procedures have been carried out, otherwise they have to rely upon "what the nurse told auntie."

I suggest that on every hospital case-sheet there should be entered the name and address of the patient's own doctor (or potential doctor); and that he should be written to as a matter of routine immediately the patient leaves hospital—whether he has sent clinical notes or not. Alternatively—as was done in the army—the patient should be given a medical card showing the diagnosis, course of the disease, operation or other treatment, and (where advisable) suggested after-treatment. If it is desired that the patient should attend hospital subsequently as an out-patient, this instruction should be given only through the patient's own doctor.

Although I am writing this chiefly in the interest of the patient, there is no doubt that the adoption of my suggestions would tend to increase the efficiency of the general practitioner, who would be stimulated to send up better clinical notes with his patients, it would lessen the congestion in the out-patient departments, and last—but perhaps not least—it would certainly be beneficial to the private practice of the respective specialists.—I am, etc.,

W. M. PENNY.

Sydenham, Sept 8th.

ORAL ADMINISTRATION OF PITUITARY GLAND.

SIR,—Since my letter on the above subject on March 2nd (p. 418) I have received a number of inquiries concerning the effect of oral administration of the gland in low blood pressure, and therefore append a further note.

The physician mentioned in Case 5 has suffered from low blood pressure all his life, and, from adolescence to middle age, from severe attacks of migraine also. When the systolic pressure fell from 105–108 mm. to below 100 he felt giddy, weak, and dyspnoeic, and had difficulty in mental concentration and memorizing. Mental and physical effort became difficult or impossible; a bad night's sleep, great physical effort, or worry frequently brought on symptoms. Clinically, no abnormality could be determined in the heart or blood vessels, and the electro-cardiographic and x-ray examinations were entirely negative.

Two months ago, after a rather severe attack of influenza, he was invited to stay with friends for a week-end. He did not yet feel quite himself, but was able to keep going until he helped his host to move a zoological specimen weighing about six pounds from one shelf to another. Although in the fifties, he still retains much of the strength which he possessed as an athlete over thirty years ago; yet in the comparatively trivial effort thus involved, he felt at once so weak that he could hardly hold up his head, and every step became a distinct exertion. His pulse was 58 and very feeble, and his systolic blood pressure was just under 100.

He received 1 grain of pituitary whole gland an hour later; in two hours from that time his pulse was 72 and easily felt, and the blood pressure 122-78-44. He then felt so fit and well that he could walk fast without any effort whatever. The marked change was extraordinary.

He has had several similar experiences, and pituitary administration has never failed to help him. Twice when he fainted, following great physical effort, no pituitary treatment was available, and there seems no doubt that had it been given to him in time he would not have fainted. At present he takes 1/2 grain of pituitary whole gland (siccum) once daily, and feels fitter and better than he has ever felt previously, walking and working without any distress or symptoms of any kind.

The important points are: There is no question that in this case small doses of pituitary whole gland given by the mouth keep the blood pressure raised in a case of congenital low blood pressure, so that life has become a joy and no longer more or less a burdoin. The whole gland preparation is used because the posterior lobe alone is rather expensive. The gland thus taken evidently supplies a deficiency in the patient's pituitary secretion. This suggests that whatever other secretion or substance in the body helps to maintain the normal blood pressure, that of the pituitary gland plays a most important part, and, further, that it acts efficaciously when given by the mouth. On the other hand, are we to look on cases of high blood pressure not due to organic changes in the kidney, etc., as the result of increased secretion in the responsible lobe of the pituitary gland? Many questions and possibilities are thus opened up.—I am, etc.,

London, W.1, Aug 31st. BERNARD MYERS.

PREVENTION OF TUBERCULOSIS OF BOVINE ORIGIN.

SIR,—At the Annual Meeting of the British Medical Association at Manchester Dr. F. H. Morison, in discussing the reduction of human tuberculosis of bovine origin (Section of Public Health, July 24th), stated that "the grading of milk has been a total failure. Certified milk has been found highly infected with tubercle." I have endeavoured, without success, to obtain the facts upon which this statement was made. As, however, to my knowledge certain medical practitioners have informed licensed milk distributors that, as a result of this statement, they can no longer recommend certified or Grade A (tuberculin tested) milk as being free from tubercle, I would like to state that, in my opinion, at the present time all dairy farms licensed by the Ministry of Health to produce certified or Grade A (tuberculin tested) milk do supply milk free from tubercle. As to the total failure of graded milk, I would point out that while in 1918 there were 18 producers and 4 distributors, in September, 1928, there were 807 producers and 3,025 distributors.

For certified or Grade A (tuberculin tested) milk to contain tubercle bacilli there must be either an inefficient tuberculin test, or what amounts to almost criminal collusion between the veterinary surgeon and the certified milk producer, which is ridiculous. It is almost impossible on a dairy farm that has been licensed by the Ministry of Health, only after thorough inspection of its hygienic buildings and surroundings, for a cow to become so infected with tuberculosis that within six months it could excrete tubercle bacilli in its milk; especially is this true now that the double intradermal test has proved so reliable that the very earliest infection is at once detected. The Certified and Grade A (Tuberculin Tested) Milk Producers' Association has for the last three years urged "that a standard of preparation and/or potency of veterinary tuberculin for diagnostic purposes be laid down, and that its sale and use be restricted to veterinary and medical practitioners." This would still further heighten the efficiency of the test, but fortunately the double intradermal test is proof against previous injections of tuberculin given by dishonest individuals.

I am still sure that the great majority of the profession do not yet realize the enormous advance that has occurred on licensed dairy farms and the high standards of hygiene and cleanliness which are kept up all the year round. They are not freak farms, and once tuberculosis has been eradicated it is not difficult, with ordinary common-sense precautions, to keep them free from this infection. The paper on the incidence of tuberculous infection in the milk supplies of Scottish cities, by Dr. Norman C. Wright (September 7th, p. 452), is a complete vindication of tuberculin-tested herds, and must reassure all those who have had any doubt on the subject. Surely his statement that "during the years 1927 and 1928 the hospitals were supplied with milk from tuberculin-tested herds, and, out *of 550 samples examined, not one sample was found to be infected*," is sufficient indication of the value of tuberculin testing in Scotland. In this country a series of examinations for tubercle in milk from tuberculin-tested herds (delivered in London) has been made since Christmas, and is still continuing, but up to date not a single infected sample has been found.

Many owners of tuberculin-tested herds feel very sore with doctors for not helping them to spread the knowledge that a pure raw milk supply is available. The demand is steadily increasing, but not as rapidly as it should; if hospitals in this country would only lead the way the general public would soon follow.—I am, etc.,

Reading, Sept. 7th. C. MADDOCK, M.D., Honorary Secretary, The Certified and Grade A (Tuberculin Tested) Milk Producers' Association.

THE NATURE OF RACE PREJUDICE.

SIR,—The conclusions to which Dr. Boas has arrived, and to which you direct attention in your interesting leading article (September 14th, p. 505), have long been held and expressed by biologists in the United States. For instance, Dr. Raymond Pearl, of the Johns Hopkins University, wrote: "I can find no manner of bitter feeling or even of regret that the pure English-Scotch-Welsh stock of the original settlers will eventually not be the dominant element in the complex of American germ-plasms that it has been in the past, though personally I am of that stock, and am, for three centuries, an American. . . . The kind of people who will survive and run the affairs of the country . . . will, I think, not be Englishmen, or Slavs, or Jews, or Italians, but *Americans*. . . . I think they will be just as gentle, as high-minded, as clever, as honourable, and as independent as any people on the face of the earth" (The Vitality of the Peoples of America, *American Journal of Hygiene*, 1921, vol. 1, p. 592).—I am, etc.,

London, W.1, Sept 14th. M. D. EDER.

Obituary.

FREDERICK FOORD CAIGER, M.D., F.R.C.P.,

Emeritus Physician to St. Thomas's Hospital; late Chief Medical Officer, Infectious Hospitals Service, Metropolitan Asylums Board.

DR. F. F. CAIGER, whose death was announced last week, was born in London in 1860. He entered St. Thomas's Hospital as a medical student in 1878, and obtained the diplomas M.R.C.S. in 1882 and the L.R.C.P. in the following year, when he also graduated M.B., B.S.Lond. In 1886 he proceeded M.D.; in 1891 he became M.R.C.P., and was elected F.R.C.P. in 1900. Caiger was a very distinguished student, and during this period he obtained various honours, both in his medical school and at the University, the chief being the Mead medal at the former and the gold medal at the B.S. examination in the latter. He filled all the important resident posts at the hospital, and some indication of his future interests became evident when he obtained the D.P.H.Cantab. in 1888. He served on the council of the College from 1918 to 1920, and was Bradshaw Lecturer in 1904, taking as his subject the treatment of typhoid fever. To the end of his days he never lost touch with St. Thomas's Hospital, and frequently and lovingly responded to its calls upon his special experience. In 1921 he was accorded the signal and well-deserved honour of being elected an emeritus physician; he then, and ever afterwards, regarded that distinction as the highest and most gratifying of his career.

After a voyage to the East as surgeon in one of the P. and O. liners, he entered the service of the Metropolitan Asylums Board in October, 1887, as an assistant medical officer at the Northern Hospital, Winchmore Hill, which was being opened as a convalescent hospital for scarlet fever patients; he served in that and the North-Western Hospital till 1890, when he was appointed medical superintendent of the South-Western Hospital at Stockwell, where he remained, with two intervals of several months each, till he retired on reaching the age limit in October, 1926. The intervals were those in which he was entrusted by the Board with the equipping, staffing, and opening of the Fountain and the Grove Hospitals, the former in 1893, the latter in 1899. The opening of the Fountain Hospital was a notable achievement on the part of all concerned, and especially of the architect, the contractors, and the medical superintendent. Accommodation for fever cases was most urgently required. The hospital was described at the time as a "temporary building," but though wood constituted a large part of the materials used for its building it was, in fact, very substantially constructed, and is still, after thirty-six years' constant occupation, in use, though now as an institution for mentally deficient children. At its opening it contained accommodation for 466 patients and 124 staff; yet it was erected, equipped, and ready for use in sixty-eight days.

In August, 1921, the tragic death of Dr. H. E. Cuff left vacant the post of principal medical officer to the Metropolitan Asylums Board. The conditions of the office were somewhat altered, and Caiger, while remaining in charge at Stockwell, was appointed chief medical officer in the Infectious Hospitals Service, and a year later chairman of the Scientific Advisory Committee of medical experts, which was set up after the death of Sir G. Sims Woodhead, the Board's bacteriological expert. The former of the two posts is one which requires the possession of much tact and discretion on the part of its holder, since he may in the course of his duties be called upon to review the judgement of one or other of his colleagues, or to advise a course of action which is not altogether in accordance with their views. It speaks much for Caiger's possession of the necessary qualifications that his relations with his colleagues were always of the most friendly nature, a remark which is also true of his relations with the Board and its various committees. Under his guidance the wheels of administration ever ran smoothly. For thirty-six years he was lecturer on infectious diseases at the South-Western Hospital, and for some time also at the Royal Army Medical College. The writer of this notice has heard medical practitioners who had been students under Caiger express the highest appreciation of the value of the instruction he imparted. He always took the keenest interest in the welfare of his staff, to promote which he would not spare himself in the least. He was one of the founders of the Fever Nurses' Association, of which he was at one time president, and till his death honorary treasurer. He was a delegate of the Association on the Central Committee for the State Registration of Nurses, which did so much to bring about the Nurses' Registration Act of 1919.

In 1900 he served on a committee of the Royal College of Physicians, appointed to consider the vexed question of "return cases" of scarlet fever, and in 1904 he was selected as a member of the important committee instituted by the Army Council to report upon the value of antityphoid inoculation. After the war he rendered valuable service as a member of the governing body and executive committee of the Enham Village Centre for the treatment and training of disabled ex-service men. Nor was he idle after his retirement, for he undertook consultative work, especially in connexion with institutions, and acted as examiner for the diploma of nursing of the University of London. He was not a voluminous writer; he was, indeed, especially during later years, too much immersed in his official duties to do much writing. But he contributed a considerable number of excellent articles on infectious diseases to standard textbooks and medical journals; one of his best was his account of scarlet fever in Allbutt and Rolleston's *System of Medicine*. He was the first to draw attention to the not infrequent concurrence of more than one infectious disease in the same patient, in a paper read before the Epidemiological Society in 1894. He frequently brought his sound critical abilities and valuable knowledge to discussions at the Royal Society of Medicine, the Society of Medical Officers of Health, and the British Medical Association, of which he had been a member for many years.

During his youth Dr. Caiger took an active interest in outdoor sports; in late years he confined himself to golf, of which he was no mean player, but he enjoyed an occasional jaunt after trout with a fly-rod. He was also fond of travel. He was of striking appearance, being tall and of fair complexion, spare but muscular, and well set up, and always well groomed. Of a kind, lively, and genial disposition he made friends wherever he went,

amongst children as well as adults. He was much more ready to see the good than the ill in those with whom he had dealings; it saddened him to censure a subordinate official, and only reluctantly would he reject a nurse at an examination. Nevertheless, his varied administrative offices were carried out with strict impartiality and firmness, and a strong sense of duty to those whose officer he was. He is mourned and will be greatly missed by a wide circle of friends, outside the medical profession as well as within it.

In 1895 he married Miss Madeline Orr, the daughter of Alexander Orr, a landed proprietor in Australia. They received an irreparable blow when their only child, Stewart, was killed whilst serving with the Royal Artillery in France in 1916. Mrs. Caiger survives her husband.

In the course of an address at the funeral service, on September 10th, the Rev. G. D. B. Poole, chaplain to the South-Western Hospital, said: We are met together at the grave of one whom we shall remember, not only as a skilled doctor, but also as a true, loyal-hearted friend. Frederick Foord Caiger became chief medical officer of the fever hospitals under the Metropolitan Asylums Board, and for thirty-six years, till his retirement in 1926, he was medical superintendent of the South-Western Hospital, where throughout the long period of years all the staff owed a great debt to the friendship and interest which he so freely gave. He was a doctor to his finger tips and devoted to his profession, and he maintained its highest and most honourable traditions. But on this occasion it is not mainly as the skilled doctor that we think of him, but as the true and loyal-hearted friend. He had a great capacity for friendship, and the friends he won he retained. Proud though he was of his profession he did not allow the doctor to obscure the man. He was the life and soul of tennis parties and other social events arranged in connexion with his hospital. The tall, well-set-up figure was familiar to all, and if Caiger was not there things seemed somewhat to flag. It would be hard to overrate the influence of his interest and friendship on the lives of many doctors, nurses, and others with whom he came into contact. He gave himself freely, and they came to regard his friendship as one of the most valued things in life. He was reserved, with a characteristic English reserve. This was clearly manifest in the case of the great grief which marked the latter years of his life, when his only son was killed in the war. Those who knew him best were conscious that he was never the same after that; there was an indefinable atmosphere of sadness about the man. But outwardly things went on just as before; there was still the same devotion to his work, the same rigid attention to detail, the same unsparing giving of himself; but all the time this grief was there, none the less real because it lay so deep. So we commend his soul to God, and we lay his body in the earth, with grateful memories of a "physician rightly much beloved" and a brave, loyal-hearted gentleman whom it is a privilege to have known.

[The photograph reproduced is by Elliott and Fry.]

We regret to record the death, in his forty-sixth year, of Dr. WILLIAM ALEXANDER WATSON, which took place in Norwich on August 21st. Son of Dr. Henry Watson, William Alexander Watson was born in Norwich, and received his medical education at Mareschal College, Aberdeen, where he graduated M.B., Ch.B. in 1908. Having been house-physician and house-surgeon to the Norfolk and Norwich Hospital, he was appointed honorary surgeon to the Jenny Lind Infirmary, honorary physician to the Scots Society of St. Andrew, Norwich, and surgeon to the Norwich City Football Club, of which he was an enthusiastic supporter. During the war he saw active service in East Africa, and on his return to Norwich he joined Dr. Philip Murphy in an extensive private practice, becoming one of the best known and most highly esteemed practitioners in the city. He was an active member of the Norfolk and Norwich Panel Committees, and a member of the British Medical Association. William Watson was an ardent golfer, and by his death the Royal Norwich Golf Club loses one of its most popular members. He is survived by his widow and two children.

Dr. DAVID NICOL ANTON, who died on August 30th, received his medical education at Dundee; he graduated M.B., Ch.B. at St. Andrews University in 1912. During the war Dr. Anton held the commission of captain in the R.A.M.C., and served in Mesopotamia. He subsequently engaged in general practice in Lochee, Dundee. He was a member of the British Medical Association.

Dr. ARCHIBALD MASON, who died, after a very short illness, at his residence, Portland Road, Kilmarnock, on September 1st, had visited patients so recently as two days before his death. He received his medical education at Glasgow, where he graduated M.B., C.M. in 1896, and proceeded M.D. three years subsequently. He obtained the diploma D.P.H. of the Royal Colleges of Physicians and Surgeons of Edinburgh and Glasgow in 1903. Dr. Mason began to practise in Kilmarnock about twenty-five years ago, and he held several public appointments. He was medical officer to Kilmarnock parish council, surgeon to the burgh police, and visiting physician to Kairnshill Sanatorium. He was in his fifty-sixth year, and was unmarried.

Dr. WILLIAM JOHN PEACOCKE, who died on September 10th at Warrington, in his sixty-seventh year, was a native of Kilrush, County Clare, and had practised in Warrington for forty-two years. He received his medical education in Galway and Dublin, obtaining the diploma L.R.C.S.I. in 1885 and the L.R.C.P.I. and L.M. in the following year. He was medical officer and public vaccinator for the No. 1 District, Warrington Union, and medical officer to the Padgate Cottage Homes. He was one of the oldest members of the British Medical Association in the Division, to which he was very loyal. He took a keen interest in sport, and was a foundation member of the Warrington Golf Club; he was a fine player, and won the Balfour Cup and several captain's medals. The funeral, on September 12th, was attended by the mayor, and a large number of his friends and professional brethren. A colleague writes: A distinctive personality has passed from Warrington and district, and Dr. Peacocke will be missed for many a long day.

The following well-known foreign medical men have recently died: Geh. Med.-Rat Professor FRIEDRICH AHLFELD, formerly professor of obstetrics and gynaecology at Marburg, aged 86; Dr. FRANCESCO CARUSO, professor of clinical obstetrics at Catania; Dr. LEOPOLD PULVERMACHER, a Berlin dermatologist; Dr. ARTHUR SOLOMON LOEVENHART, professor of pharmacology and toxicology at the University of Wisconsin Medical School; Dr. JOHN ALEXANDER WITHERSPOON, professor of clinical medicine at the Vanderbilt University Medical School, and formerly president of the American Medical Association, aged 64; Dr. CHARLES E. DE M. SAJOUS of Philadelphia, professor of endocrinology in the University of Pennsylvania, aged 76; Dr. DUCROQUET, surgeon to the Hôpital Rothschild, Paris; and Dr. HERMANN WIELAND, professor of pharmacology at Heidelberg, aged 44.

The Services.

DEATHS IN THE SERVICES.

Deputy Inspector General Charles William Buchanan-Hamilton, R.N. (ret.), died at Southsea on July 13th. He was a nephew of James Buchanan, President of the United States before Lincoln, and at first intended to enter the Church, but changed his mind and adopted the medical profession, studying in the Royal College of Surgeons School in Dublin, and taking the L.R.C.S.I. and L.R.C.P.Ed. in 1873. He entered the navy as surgeon on June 4th, 1878, reached the rank of fleet surgeon on July 15th, 1894, and retired, with an honorary step as deputy inspector general, on July 26th, 1907. In the Egyptian war of 1882 he served in H.M.S. *Beacon*, and took part in the bombardment of Alexandria, the seizure of the Suez Canal and of Port Said, Suez and Ismailia, receiving the medal with a clasp and the Khedive's bronze star. In the

Sudan campaign of 1884 he served as surgeon of the Royal Marine battalion, of the Royal Victoria Hospital at Suakin, and of H.M.S. *Sphinx*, gaining a clasp to the Egyptian medal. In the Burma war of 1885 he served as surgeon to the Naval Brigade, and was present at the occupation of Mandalay, receiving the medal with a clasp. He qualified as interpreter in Hindustani and Persian. His last appointment before retirement was fleet surgeon of Sheerness gunnery school and dockyard.

Surgeon Commander Devonshire Penrose Hawkes Pearson, R.N. (ret.), died at Rowland's Castle on July 22nd. He was the younger son of Mr. John Pearson of Mountcross, County Cork, and was educated at University College, Cork, taking the L.R.C.P. and S.I. in 1912. Entering the navy as surgeon on April 11th, 1913, he reached the rank of surgeon commander in 1925, and retired on May 16th, 1928. During the first year of the war he served on H.M.S. *Antrim* in the Grand Fleet; in January, 1916, he was sent on special duty to the Mediterranean; and in June, 1918, was appointed senior medical officer on a new cruiser, H.M.S. *Danaë*. For some time prior to his retirement he was serving at the naval barracks in Portsmouth.

Colonel Thomas John Rashleigh Lucas, C.B., Army Medical Service (ret.), died in London on July 23rd. He was born at Bandon, Cork, on April 7th, 1858, was educated at Trinity College, Dublin, where he graduated as M.B. and Ch.B. in 1880, and entered the A.M.D. as surgeon on February 5th, 1881. He attained the rank of colonel on January 2nd, 1910, and retired on January 2nd, 1914, being subsequently re-employed during the great war, from August 5th, 1914. On January 29th, 1906, he was appointed commandant of the depot of the R.A.M.C. at Aldershot, and held that post till his promotion to colonel. He served in the Egyptian war of 1882, when he was present at the action of Kassassin and the battle of Tel-el-Kebir, was mentioned in dispatches, and received the medal with a clasp and the Khedive's bronze star; in the Sudan campaign of 1884 he was present at the battles of Teb and Tamai, mentioned in dispatches in the *London Gazette* of May 6th, 1884, and received two clasps; in the Nile campaign of 1884-85, with the camel bearer company, he saw action at Abu Klea and Metemmeh, receiving two clasps; and he served in the Frontier Field Force in 1885-86. He also served in Burma in 1892-93, in operations in the Northern Chin Hills, being mentioned in dispatches in G.G.O. No. 733 of 1893, and receiving the Indian Frontier medal with a clasp. In the South African war of 1899-1902 he was in charge of No. 4 General Hospital, took part in the relief of Ladysmith, and served in operations in Natal in 1899 and 1900; he was mentioned in dispatches in the *London Gazette* of February 8th, 1901 (Sir R. Buller's dispatches of March 30th and November 9th, 1900), and of September 10th, 1901, received the Queen's medal with one clasp, and the King's medal with two clasps, and also the C.B.

TESTIMONIAL TO SIR RONALD ROSS.

FIFTH LIST OF CONTRIBUTORS.

On May 11th we published a letter announcing that a fund, called the Ross Award Fund, was being started in order to give some recognition to Sir Ronald Ross for his discoveries on the mode by which *malaria is carried, and for his lifelong* efforts regarding the prevention of that disease. The letter stated that donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15, cheques to be crossed "Ross Award Fund a/c." The names of those who had contributed to the Fund up to May 17th were printed in our issue of June 8th (p. 1065); a second list of donors appeared on July 13th (p. 76); a third list on July 20th (p. 129); and a fourth on August 17th (p. 328). We now print a further list of those whose donations, amounting to £1,247 14s. 6d., were received between July 13th and August 10th. The total amount of the Fund on August 10th was £7,585 13s. 7d., which included £2,000 contributed by readers of the *Straits Times*, Singapore. The list published below does not include anonymous contributors or contributors whose initials only have been supplied.

H. Allan, F. Ackroyd, Mrs. Norman Aldridge, Miss L. S. J. Aston, Daniel Adamson, M. A. Anderson, J. D. Ashworth, S. Alexander, George Ayre, *Mrs. Annesley, Miss J. C. Adams, Mrs. J. H. Allan, E. Armstrong, F. H. Alton, Mrs. A. C. Amos, W. R. Allin, Miss Janie Allan, Mrs. Angold,* Gladys Ashmole, J. M. C. Austin.

Professor Blair Bell, Dr. Victor Bonney, Miss Edith Brodie, Mrs. G. M. Bradley, R. W. A. Barclay, Mr. W. F. Bradshaw, Rev. and Mrs. Brotherton, Mrs. Bailey, P. D. Boothroyd, R. W. Blakeley, William D. Bosanquet, E. Maurice Besley, Miss Barlow, H. Holman Berry, the Misses Bragg, Frank N. Butler, E. du Boulay, Mrs. Buckely, E. D. Butler, H. G. Brown, Mrs. Brunner, Directors, Messrs. Boots Pure Drug Co., Ltd., F. Barrington, Brandon, Miss E. H. Barwell, N. Boyce, Mrs. Burton, Mrs. O. Brackenbury, Mrs. Barber, Miss Edith M. Beadle, Mrs. Bolton, Mrs. Lucy Beer, Mr. and Mrs. H. R. Bilbrough, Major J. S. Biscoe, Mr. and Mrs. Blyth, Mrs. Ralph Berners, Mrs. Bogle-Smith, Mrs. Battcock, Miss Bannister, Mrs. Beresford, Miss Constance M. Birley, Mabel Byard, A. W. and Jane Bradshaw, Miss Barnes, S. M. Bell, Violet Lady Beaumont, Mr. H. Massac Buist, Mrs. Ellen A. E. Buchanan, K. Birch, Commander James Brant, R.N., George Bedford, Mrs. Houghton Baldwin.

Dr. T. E. A. Carr, *Sir Aldo Castellani, Dr. R. Crichton, Dr. Charles P.* Coxwell, Rev. H. W. Cope, A. M. Crawford, Ellen L. Clark, Mr. M. Cary, Hig[illegible] Mrs. F. M. Cother, Mr. and Mrs. A. J. Cor[illegible]lins and Sisters, A. A. Cameron, Miss E. [illegible] Miss Carrick, Miss H. R. Clark, A. J. Coc[illegible] Crawshaw, *Mrs. Albert J. Chalmers,* Mis[illegible] Walter Cook, Mrs. Crossley, L. Clarke, Lil[illegible] G. C. Clarence, Lieut.-Colonel Campion Cander, M. Clarkson, Beatrice Colonna.

Sir Godfrey Dalrymple-White, Bt., Dr. H. Bryan Densham, Dr. A. B. *Dalgetty, Gomer B. Davies, M. Dolton, Miss Dow (Canada), H. Stewart* Dunford, Matthew Davidson, Colonel H. D. Ditmarsh, N. Dodd, A. E. Douglas, J. Henry Dugdale, E. D. Durham, E. J. Down, A. Craigie Daniell, Hon. Mildred Dodson, Lady Conan Doyle, D. Dennis, Dorothy Davidson, G. N. Drury.

Dr. Edmonds, Thirza J. Endicatt, Mrs. S. Eustace, Mrs. Emerson, Mrs. Charles Evans-Gordon, Mrs. C. Dyer Edwards, Mrs. A. C. Eberall, S. G. Elton.

Colonel Sir W. Y. Foster, Miss L. Foley, Mrs. Catherine Finn, J. L. Forrester, Miss Fuller, Messrs. Ford and Brown, Miss D. Field, Mr. and Mrs. B. C. Forder, Mrs. Furse, Miss A. G. and Miss N. E. Ferns, M. Fox, Florence A. Fraser, T. Burdon Frazer, Miss F. G. Fisher, Miss Feilden, Mrs. de Freville, Mrs. Fitzmaurice, Mrs. Forbes and Mrs. Roberts, Mrs. J. Lee and Emily Finney.

Major-General R. W. Gowan, Dr. Gibson, B. Green-Armytage, Miss A. Giles, Mrs. Gavine, Mrs. G. Goodman, Mrs. Gurney and Miss Kidd, Miss Gaine, Mrs. and Miss Gaskell, J. G. Grundy, Miss F. Greaves, Miss M. E. Greaves, John Grier, Timothy Gardiner, E. F. Gaskell, Edith Gaitskell, Miss J. Gilstray, A. J. Goulden, Melville Gray, E. S. Gaines, Mrs. Eleonaro Gibbon.

Lieut.-Colonel Herbert Herbert, F.R.C.S., Cecilia Hammond, Mrs. C. E. Hall, Cecil J. Hackett, Mr. F. H. Hamilton, Mrs. Hart, E. Holiday, S. E. Higgin, Fred. J. Hayes, D. M. Hanschell, Mrs. N. M. Higham, Miss M. Heyworth, Mr. and Mrs. William Hay, M. D. Hill, L. Hutchins, Mrs. Alfred Hewitt, George Heath, The Misses Heard, Mrs. Higginson and Miss Florence Verrall, Mrs. Herbert Hodson, Miss Harris, Mrs. Hill, Mrs. Annie Elizabeth Helder, Mrs. E. M. Hendry, J. T. Darcy Hutton, Beatrice Hulme, E. Hinks, H. J. *Hare, Lady Hammond, Mrs.* Haynes, M. Hickson. A. E. Ivory.

Lieut.-Colonel H. J. Jones, Jorehaut Tea Co., Ltd., *Miss Joicey, S. Derwen* Jones, F. M. Jobson and M. Jobson, Miss Fanny Johnson, S. P. Jones and H. J. Williams, Mr. F. Jackson, Mrs. A. F. Jennings, N. J. Jacob, Miss Jeffery.

R. A. Kemp, Reginald Kennedy, Mrs. Ellen Knowlson, S. Kershaw, A. Knox, Mr. H. *Kirby-Smith.*

Professor R. T. Leiper, F.R.S., Liverpool University Guild of Undergraduates, Lord Lamington, Miss E. C. L'Estrange, Iris H. Little, Arthur Loney, Lady Lyne, Miss E. G. Lupton, J. P. Lund, Mrs. H. Lomax, A. Lindsay, W. Langham-Carter, Miss Law, A. L. and E. V. Lindsay, Sir Sidney Low, J. E. Ludlam, L. M. *Lough, Miss Lowry,* Mr. J. W. Laing, W. F. Latimer, Leinster House School Boys.

Sir Ewen Maclean, Dr. Charles Miller, Dr. *MacLaughlin,* Dr. Edward E. Moore, General G. H. and Mrs. Mullens, J. P. Morton, Miss E. Miller, G. F. Montgomery, Mrs. R. F. Martin, Miss Enid M. Milnes, L. Maw, Mrs. Mary Moore, Miss McKay, Mrs. G. McNaughtan, Mr. John Mulloch, Robert McDougall, J. S. Marphail, Mrs. Marshall, L. G. Mason, A. Milnes, D. Misplon (Livingstone), J. A. Morris, H. S. McKeague, J. M. McLaren; Mr. Maurice G. McKean, Miss S. Moberly, Mrs. Meineck, Mr. R. Monckton, James Legge Morton, Mrs. Edith Maclean, The Misses J. and E. Montgomery, C. Muggleton, Mr. and the Misses Maclaren, Mrs. Mackinochie, Leonora Maclean, S. G. Maartenez, Miss L. Martyn, E. E. Mocatta and friends, Marian Masketer, Miss Murray, J. H. Marlow, M. Judith Massey, Ellen M. Mayne, S. Martin, R. J. Moutries, E. C. Marchant and E. Edwards, Nurse McCartney, Mrs. W. F. de B. Maclaren.

Maud M. Nash, Mrs. W. Noves, Mrs. M. Beatrice Negus, Robert Nichols, Miss Neilson, Mrs. Nath, C. S. Poyntz, Mrs. Nuttall, W. Spencer Newton, Nigeria Association of European Civil Servants.

Mr. A. B. Ould, S. F. Oakley, Mrs. N. M. Orpen.

Lord Playfair, Dr. S. Vere Pearson, Dr. John Playfair, Mrs. Pierrepont-Barnard, N. Parker, G. B. Palmer, H. H. Parker, Mary S. Perry, J. de R. Phillip, Ransom Pickard, Edwin Perry, Mrs. A. B. Partridge, Mrs. L. Pym, M. Phillips, Rev. Edwin and Mrs. Pyper, G. A. and E. E. Please, Agnes Pearson, Mildred A. Paine, Miss Pearson, Lady Patey, Mrs. Herbert Parke, P. Preston, Mrs. Parsons.

Mrs. Quirk.

Lieut.-Colonel G. G. Russell, Major C. E. Roberts, Miss Rowland, The Misses Ryder, James Riley, Annie G. Roberts, Mr. F. W. Richardson, E. C. Ridding, John T. Roberts, A. R. Richardson, Miss K. Randall, Miss J. J. Raven, O. Randle, Miss Rae, J. H. M. Robertson, Robert R. Ross, *Joseph Rochford, Mary L. Robinson,* Miss Sylvia C. Rathbone.

Dr. Marie C. Stopes, R. D. Sistern, T. Waring Shaw, Fred Skull, G. T. Skipworth, Collected by Miss C. E. Slade, Miss E. Scoones, Miss C. J. Shepheard, E. Smith, E. and L. Scott, Mr. Compton Smith, Lady Margaret Sackville, Mrs. Snow, M. E. Smyth, Miss R. Sheehy, R. E. R. Squibbs, Miss Stevens and friends, Mr. R. F. Skrimshire, I. Severs, B. Severs, Miss R. A. Storran, Lilian Shaw, Alice M. Seymour, V. Sealy, M. A. Sanderson, Miss M. K. Sasse, Roland G. S. Street, Miss Joyce E. Sweeney, James E. Sanderson, R. H. M. Sandemann, Mrs. N. F. Scott, Captain E. S. Steward, Maria Slater, H. A. Sams, Miss M. S. Sorley, Mrs. Gilbert Stratton, J. Monsemerti Sandomini.

Dr. Mary Thorne, Sir D. J. Tata, Arthur Tipper, M. M. Twycross, Mrs. Teesdale, Edwin Thorpe, Tapl, D. A. Tanner, Mrs. E. Taylor, W. O. Taylow, Mrs. Treble, O. M. Thresher, G. B. Tickton.

Miss B. Veale, Rev. H. J. Valentine, Mrs. Valentine, Miss Vaughan-Barber, Mrs. Vere-Jones, Mr. and Mrs. E. Vulliamy.

Dr. P. Watson-Williams, Colonel Campbell W. Watson, Ernest G. White, G. A. I. Waters, Mrs. E. Wilson, C. H. E. West, Mrs. E. P. *Webb,* Margaret and Mary Wroe, Mr. Leonard J. Williams, Mr. A. Wills, T. M. Williamson, Grace Walker, K. Wood, Collected by Mr. H. C. Wreathall, Williamson, Grace Walker, K. Wood, Collected by Mr. H. C. Wreathall, Mary A. J. Waring, Mrs. J. P. Warren, John A. S. Watson, Iris Wrey, J. Wright, Mrs. Winter, Nathaniel Wilson, Mrs. E. L. Wilson, P. J. Weaver, Samuel Wright, Grace Walker, Mrs. Werring, Mr. Warner, Mrs. Wallace, Miss M. R. Windle, Mrs. E. Willis, Miss H. Walker, Miss Wearing, Brice White, W. H. Whitby, E. Wadeworth, L. Whitley, Miss Katharine Webster, A. H. Wales, Mr. M. Wright, Elizabeth P. Webb. Miss M. Youngson.

Medical News.

THE thirteenth Norman Kerr Memorial Lecture will be delivered by Sir Josiah Stamp, G.B.E., in the Great Hall of the House of the British Medical Association on October 8th, at 4 p.m., the subject being "Alcohol as an economic factor."

THE new session of the Medical Society of London will commence on Monday, October 14th, when the annual general meeting will take place at 8 p.m.; at 8.30 p.m. Mr. Donald Armour, C.M.G., will deliver his presidential address, entitled "Some of Lettsom's Contemporaries." On October 28th, at 8.30 p.m., a discussion on radium therapy will be introduced by Mr. A. E. Hayward Pinch and Professor Sydney Russ. A discussion on the relative value of the different methods of diagnosis in gastric disease will be opened by Dr. J. A. Ryle, Dr. Harrison Orton, and Professor E. C. Dodds at the meeting on November 11th, and a clinical evening will be held on November 25th. Mr. Wilfred Trotter will introduce a discussion on the treatment of head injuries on December 9th. The Lettsomian lectures on the enlarged prostate and prostatectomy will be delivered by Sir J. W. Thomson Walker on February 17th and 26th and March 5th, 1930; and Sir Arthur Keith, F.R.S., will deliver the annual oration on May 12th, 1930, his subject being "Modern medicine and evolution."

THE annual prize distribution of St. George's Hospital Medical School will take place in the Board Room of the Hospital on Tuesday, October 1st, at 3 p.m., when the inaugural address, entitled "Doctor and Patient," will be delivered by Dr. E. I. Spriggs. The annual dinner will be held at the Hyde Park Hotel, Knightsbridge, on the same day, at 7.15 for 7.45 p.m. The chair will be taken by Mr. D. Cotes-Preedy, K.C.

THE new session of the London (Royal Free Hospital) School of Medicine for Women will be held on Tuesday, October 1st, at 3 p.m., when the prizes for the last session will be presented and an address will be delivered by Dr. Janc Walker, her subject being "The return of woman to medicine."

A COURSE of six lectures on the place of psychology in general nursing will be given at the Tavistock Square Clinic, 51, Tavistock Square, W.C.1, on Thursdays, at 6.30 p.m., beginning October 3rd. The subjects to be dealt with are: the mind of the patient; the mind of the nurse; psychological methods available in nursing; psychological help in linked symptoms of body and mind; nursing of obvious nervous illnesses in general hospital; and illustrative cases from the nursing point of view. The fee for the course is 10s. 6d. for non-transferable tickets; 15s. for transferable tickets; and single tickets at 3s. 6d. will be issued if accommodation permits. These tickets must be obtained in advance from the honorary lecture secretary of the Tavistock Clinic.

THE Fellowship of Medicine announces that an all-day course in gastro-enterology will be held at the Prince of Wales's Hospital, Tottenham, from September 30th to October 4th. In October the following courses will be held: an all-day course in cardiology at the National Heart Hospital from October 7th to 19th (strictly limited to 20); an afternoon course in ophthalmology at the Central London Ophthalmic Hospital from October 7th to November 2nd; a course in tropical medicine at the London School of Tropical Medicine on Tuesday and Thursday afternoons from October 8th to 31st; gynaecology at the Chelsea Hospital for Women from October 14th to 26th; a morning course in diseases of children at the Great Ormond Street Hospital from October 14th to 26th; a whole-day course in diseases of the throat, nose, and ear at the Central London Throat, Nose and Ear Hospital from October 14th to November 2nd, comprising a clinical course and a practical operative class; and a whole-day course in medicine, surgery, and the specialties at the Metropolitan Hospital, Kingsland Road, from October 21st to November 2nd. There will also be an M.R.C.P. evening course of lectures on Tuesdays and Fridays at 8.30 p.m. from October 15th to December 6th. Copies of all syllabuses and information on all post-graduate work are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

A COURSE of lectures on the problems of personal and public health will be delivered in the lecture hall of the Royal Institute of Public Health on Wednesdays, at 4 p.m., from October 16th to December 18th inclusive, the subjects being: the health and conditions of work of medical students; broadcasting and health; the asthma problem; the possibilities and limitations of radium treatment; the influence of pathology upon maternal welfare; the early diagnosis and treatment of malignant disease; some aspects of the tuberculosis problem; dress in relation to health and disease; speed as a psycho-physiological factor in the life of to-day; and industry in relation to personal and public health. The Harben Lectures of the Royal Institute will be delivered also in the lecture hall on Fridays, October 18th and 25th, and November 1st, at 5 p.m., by Dr. R. A. Peters, professor of biochemistry in the University of Oxford, whose subject will be co-ordinative biochemistry of the cell and tissues. The annual congress of the Institute in 1930 will be held in Portsmouth, from June 4th to 9th inclusive. Further particulars of the congress and the lectures can be obtained from the Honorary Secretaries of the Royal Institute of Public Health, 37, Russell Square, W.C.1.

A COURSE of lecture-demonstrations on children's diseases will be given at the Royal Northern Hospital from October 14th to 22nd, daily at 2.30 p.m., Saturday and Sunday excepted. Fee for the course, one guinea. For further particulars apply to the dean of the hospital.

THE autumn session of training courses at the Royal Sanitary Institute for examinations for sanitary, food, and smoke inspectors, the associateship of the Institute, and of sanitary science generally, commences on September 30th. Syllabuses of the lectures are obtainable from the secretary of the Institute, 90, Buckingham Palace Road, S.W.1.

A CONGRESS of the Chartered Society of Massage and Medical Gymnastics will be held at the House of the British Medical Association from October 15th to 19th inclusive. Reduced railway rates are in force for members of the society who wish to attend the congress for the whole or any part of the period. In addition to lectures and demonstrations on various subjects, lantern lectures will be given at the Central Hall, Westminster. The first annual dinner of the society will take place at the Café Royal, Regent Street, on Wednesday, October 16th, at 7.45 p.m. The annual general meeting of the society will be held on October 19th, at 2.30 p.m. Further information may be obtained from the secretary at the offices of the society, 157, Great Portland Street, W.1.

A VACANCY has arisen at Epsom College for a Salomons entrance scholarship of £50 a year. Candidates must have been over the age of 11 and under 14 on January 1st, 1928; they must be the sons of legally qualified medical practitioners either living or deceased; they must show an adequate standard of education for their age; and their financial condition must be such as to make it difficult or impossible to obtain education at the college without the help of the scholarship. Forms of application may be obtained from the secretary of Epsom College, 49, Bedford Square, W.C.1, and when filled up must be returned before September 30th.

THE William H. Welch Medical Library at Baltimore will be formally opened on Thursday, October 17th, under the presidency of Mr. J. S. Ames. Professor Harvey Cushing of Harvard University will deliver an address, and in the afternoon there will be a conference on medical libraries. On the following day the Department of the History of Medicine of the Johns Hopkins University will be inaugurated by Professor W. H. Welch, and an address will be given by Professor Karl Sudhoff of the University of Leipzig. The afternoon will be devoted to a conference on the history of medicine, at the end of which the Harvey tercentenary film will be exhibited.

THE possible extension to India of the activities of the People's League of Health was discussed at conferences of the League on July 22nd and 29th. Dr. J. L. Pinto, Assistant Director of Public Health in Bombay, and Dr. Kathleen Vaughan, late superintendent of the State Hospital for Women in Kashmir, stated their agreement with the view expressed in 1924 by the late Major-General J. B. Smith, then Medical Adviser to the Secretary of State for India, that a society in India similar to the People's League of Health in Great Britain would be of the greatest service. After full discussion it was concluded that if a branch of the League was to be established it must be through, and become part of, the machinery already in operation in India.

DR. DUDLEY T. BIRT, senior medical officer, West African Medical Staff, Sierra Leone, has been appointed a member of the executive committee of the Gambia and an official member of the Legislative Council of that colony.

THE annual congress of German roentgenologists and radiologists will be held at Prague on October 26th and 27th, when the following subjects will be discussed:—(1) Treatment: (a) biological dosage in roentgenotherapy, introduced by Professor Hohlfeder of Frankfort [illegible] acute and subacute inflammations of testis, and prostate), introduced [illegible] (2) Cranial diagnosis: (a) roentgen diagnosis of diseases of the child's skull, introduced by Professor Schüller of Vienna; (b) roentgenology of the ear, introduced by Dr. Ernst Mayer of Vienna. Further information can be obtained from Dr. Walter Altschul, Vladislava 17, Prague.

THE thirteenth Italian Congress of Paediatrics will be held at Turin under the presidency of Professor G. B. Allaria from September 23rd to 26th, when the following subjects will be discussed: rickets, introduced by Zamorani and Auricchio; congenital heart disease, introduced by Zibordi and Fornara; and open-air schools, introduced by Gismondi.

THE evidence given on May 2nd on behalf of the Ministry of Health, and from April 18th to July 11th on behalf of associations of local authorities and local government officers, before the Royal Commission on Local Government, has just been published, and may be obtained at H.M. Stationery Office. The price of the volume is 4s. 6d. net.

AN international medical tour is being arranged by Dr. Friedrich Barach of Vienna to leave Trieste on December 12th and visit medical institutions in Greece, Egypt, and India. Inquiries should be addressed to the Aerztliche Auslands-Studienreisen, Biberstrasse 11, Vienna 1.

DR. F. J. WALDO, who conducted an inquiry into the Victoria Embankment fire on June 6th, has made the following recommendations to the Home Secretary and the Lord Mayor. He suggests that there should be a public Government inquiry into the problems concerned with such subways, with special reference to the occurrence of explosions and fires. He thinks the terms of the London County Council Subway Act of 1893 should be amended, since at present it is obligatory to lay down coal-gas mains in pipe subways together with electric cables. He advises the immediate removal or replacement of inflammable gutta-percha insulated cables by a better method of insulation. All dormant cables should be removed from the subway, and all the subways should be permanently wired for lighting according to the rules of the Institute of Electrical Engineers, thus eliminating the need for any portable illuminating appliances.

A FULL report of the conference on mental welfare held at the Central Hall, Westminster, on April 25th and 26th, has been published in book form, price 3s. 6d. The volume can be obtained from Miss Evelyn Fox, honorary secretary of the Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1. We printed a report of the proceedings in our issue of May 4th (p. 817).

THE Water Pollution Research Board of the Department of Scientific and Industrial Research publishes periodically in typescript a summary of current literature bearing on water supplies, sewage, trade waste waters, river pollution, and allied subjects. The issue dated August, 1929, may be consulted by members in the Library of the British Medical Association.

WE are informed that A. Fleming and Co., Government contractors, 39, Victoria Street, London, S.W.1, have generously offered to present a large part of their surplus stock to hospitals, infirmaries, cripples' homes, and similar institutions making sufficiently early application. The offer includes wooden arm splints (Clarke's pattern); iron dorsiflexed wrist splints; iron humerus and leg splints; wooden back of leg and thigh splints, hinged at the knee; arm extension splints; extension apparatus of the Guy's pattern; and iron bed cradles (Lawrence's pattern). It is stated that all the articles, though slightly shop-soiled, are quite new and in a serviceable condition. They will be packed free of charge, but dispatched carriage forward. Institutions interested are asked to apply for a complete and illustrated list of the stock available for disposal in this way.

THE *Liverpool Medico-Chirurgical Journal*, which was suspended in 1916, has now been revived, and will be delivered free twice a year, in July and January, to all ordinary members of the Liverpool Medical Institution. It is also obtainable from Messrs. H. K. Lewis and Co., Ltd., of 136, Gower Street, W.C.2, at the price of 2s. 6d. The July issue contains the presidental address by Dr. John Hay, which was devoted to William Harvey. Dr. C. O. Stallybrass contributes an article on acquired immunity in human communities, and Mr. R. Watson Jones one on the treatment of fractures by intramedullary pegging. Other clinical articles include notes on some haemorrhagic conditions, by Dr. W. Howel Evans; the diagnosis of chronic myocarditis, by Dr. I. Harris; some observations on the effect of lead on the tissues, by Dr. M. Datnow; the treatment of varicose veins by injection, by Dr. Stuart McAusland; and vision and vocation, by Dr. C. Alston Hughes. An account of the transactions of the Liverpool Medical Institution and book reviews complete an interesting issue of a journal, the reappearance of which we welcome with congratulation.

PROFESSOR LEPOUTRE of the Lille medical faculty has been presented with the Golden Cross of Merit of Poland.

SANITÄTSRAT DR. PRINZING, director of German medical statistics, has recently celebrated his seventieth birthday.

PROFESSOR J. WAGNER-JAUREGG has been elected an honorary member of the Vienna Academy of Sciences.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

RELIEF OF PAIN IN OSTEITIS DEFORMANS.

DR. W. M. M. JACKSON (*Folkestone*) asks for advice in the treatment of a man, aged 64, who has osteitis deformans, and is seriously disturbed at night by pain in the shin. The pain comes on after he has been in bed for about an hour, and persists more or less all night. Ultra-violet rays and thyroid extract have been tried without much success. Dr. Jackson would welcome suggestions as to how relief may be obtained, and whether any British or foreign spa treats this condition.

INCOME TAX.

Expenses of Post-Graduate Course.

"R. H. A." inquires whether the expenses incurred in taking a post-graduate course can be treated as deductible for income tax purposes.

*** No; they are analogous to capital outlay, inasmuch as they constitute expenditure to improve earning capacity over a future period.

Basis for Calculating First Year's Earnings.

"CANSTIAN" recently bought a practice, also purchasing the outstanding book debts. On what basis should he return the first year's earnings?

*** The most convenient course will be to adhere to the cash basis as regards receipts, bringing into the account not only his own fees, but also the sums taken in respect of the purchased debts, and in the circumstances the inspector of taxes may not object to that being done. But the correct basis is to exclude receipts from the purchased debts and to calculate his gross income at (1) the cash received for his own work, *plus* (2) the value of the outstanding debts due for such work at the end of his first year.

Allowances Shared with Taxpayer's Wife.

"CRENOS" sends particulars of his own and his wife's income, explaining that they are separately assessed on their own request, and inquiring whether the allowances in his case appear to be correctly calculated.

*** So far as we can check the figures from the material supplied the allowances seem to have been correctly divided, provided that the approximate figure given for the wife's income represents the net amount after deduction of tax. It has to be borne in mind that fluctuations in the wife's income will affect the ratio between her income and his own, and therefore the amount of the allowances made to him. The annuity ranks as income of the year in which it is received, and therefore affects the year 1927-28 if—as we gather from the figures—it was purchased in that year.

Motor Car Replacement and Depreciation.

"F. C. B. G." had a car which had cost £315 and sold it for £55 in September, 1927, buying a new car for £334. The loss on sale—that is, £260—was allowed as a professional expense of the year 1927, but as the assessment for 1928-29 was based on a three years' average, only one-third of that amount actually went to reduce his liability. He also cl
the new car for the period Sept
deduction for the year 1928; this

*** There is a sharp distinction between the deduction of replacement cost as one of the professional expenses of the year

in which it was incurred and the depreciation allowance, the latter being a specific deduction from the profits as calculated for assessment, whether on a three years' average or any other basis. It follows that no depreciation claim could be made for the particular period, September to December, 1927. Any allowance due would have to be claimed as for the financial year 1928-29 and onwards. There is, however, a rule laid down in one of the leading cases that "renewals" and "depreciation" cannot be allowed on the same assessment, and that bars out the depreciation claim for 1928-29 in the circumstances. Consequently our correspondent must forgo that allowance for 1928-29, but can claim it for the following years, and in the long run it need make no difference, provided that he claims "obsolescence" when he replaces his present car, because only the amount of the depreciation actually is then taken into consideration. The fact that the change over from the three years' average deprived him of two-thirds of the effective replacement allowance does not give any ground for relief.

LETTERS, NOTES, ETC.

RELIEF OF PAIN.

DR. ELIZABETH MUDIE (Glasgow) writes: I was most interested by Dr. Herbert Cardin's note on the relief of pain (September 7th, p. 482), and am very grateful for the hint about amyl nitrite. Perhaps my own first-aid treatment of burns and scalds will be of interest, also known to me for 30 years. Raw potatoes are cut in halves and finely scraped; the pulp thus obtained is laid upon the painful area, just as a thick poultice. This treatment can be repeated in an hour if the pain persists, but one good application is usually sufficient. Whenever I myself get a painful burn from whatever cause I find that five minutes' exposure of it at five inches from a quartz mercury lamp takes away all the pain. This discovery was made in the first instance quite by accident. I had to attend a patient immediately after scalding my wrist badly with boiling oil. When the patient left my pain had gone. Since then my staff have always resorted to the lamp for relief in accidents of this kind.

DAMPNESS IN DWELLINGS.

DR. F. G. CAWSTON (Durban) writes: When considering the prevention of dampness in dwellings further attention should be paid to artificial methods, whereby ventilation is secured by means of an inlet at each corner and an outlet at the summit of corrugated iron roofs. The free ventilation thus obtained not only helps to prevent dampness, but is of great value in overcoming the inconvenience caused throughout the tropics by the constant accumulation of hot air in contact with metal exposed to the tropical sun. Climatic conditions often favour the use of iron roofs in preference to tiled ones, in spite of the coolness of the latter, but their use is often detrimental to the storage of medicines and food. The various devices at present in evidence are quite inadequate to insure sufficient ventilation of roofs, even as a supplement to adventitious draughts.

THE FATE OF A NEEDLE IN THE BODY.

DR. J. R. BEAGLEY (Thatcham, Berks) writes: A female patient came to me in June, 1928, having run a broken rusty needle into her right breast. I sent her to hospital, but the needle was not found, and she was told to return if it gave rise to trouble. Since that time she had had a series of boils involving both upper and lower limbs, face, and chest. Her latest "boil" was of linear shape, and was situated at a spot about half-way down the right forearm. I incised this, and withdrew the rusty needle, fifteen months after its entry into the patient's breast.

OPEN-AIR SCHOOLS IN FRANCE.

THE value of open-air schools is emphasized by Dr. P. F. Amaud-Delille, who contributes an illustrated article to the *Paris Méd.cal* for August 3rd. He contends that such schools should no longer be reserved for the delicate, since all children benefit from fresh air and sunshine. The ideal arrangement, according to him, is for the class-rooms to be open to the south-east, with windows preferably permeable to the ultra-violet rays. Radiators by the windows will be necessary during cold weather. The time-table recommended for residential schools as, *mutatis mutandis*, for day schools, is as follows: 7.30 or 8 a.m., half an hour's exercises in the open air, followed by breakfast; one hour's class-work; *half an hour for play*; *another hour's work*; half an hour of organized games, and, if time permits, another period of study. At 11.30 a.m. a hot shower-bath is given, and is followed by a cold one. At noon dinner occupies 30 to 40 minutes, 20 minutes being allowed for play. From 1 to 2 p.m. the children sleep in the open air; the next hour is devoted to breathing exercises and games in the open air. From 3 to 4 a class is held, and tea is taken at 4 p.m. Free play follows from 5 to 6.30, and then a class for half an hour, with supper at 8 p.m. The children sleep with windows wide open or, preferably, on balconies roofed over but open at the sides. The minimum of clothing is worn all day. Generally the body and limbs are bare, but in the winter more clothing may be put on. Dr. Amaud-Delille states that the improvement in physique and in morale is remarkable after a period of three to four months at such a school. A flabby, doleful boy with round shoulders, winged scapulae, and protuberant abdomen becomes a bronzed, firm-fleshed, erect, active, cheery individual.

DRUGS AND INSANITY IN EGYPT.

IN his report for 1927 on the Government mental hospitals of Egypt (Government Press, Búlâq, Cairo, 1929) the Director of Lunacy makes the following observations under the heading "Drugs and Insanity": "About 100 cases have been admitted *during the last year whose mental derangement was considered* to be due entirely to drugs, and drugs alone; this number does not include by any means all those cases who took drugs and aggravated an already existing insanity or mental defect. I am, however, of the opinion that there are very few entirely normal persons who take drugs to the extent of upsetting their mental equilibrium, and that the mass of drug addicts are made up of weak-minded persons, degenerates, and mildly insane, and that their addiction to drugs in the beginning is either due to their inability to say 'No' amongst bad associates, or it is an effort on their part to improve their recognized inferiority. For their immediately destructive properties cocaine and heroin head the list, but it would be difficult to determine any one drug as being less harmful than another when their remote effects are considered. For instance, hasheesh and other drugs or gland extracts taken as aphrodisiacs account for very few cases in an acute stage, but who can tell their ultimate action on a normally failing sexual power? I have noted several cases lately which have been difficult to classify amongst the ordinary forms of insanity, and they had been taking reputed aphrodisiacs in large quantities; they resemble superficially, in many of their aspects, cases of general paralysis of the insane."

THE N.S.P.C.C.

THE National Society for the Prevention of Cruelty to Children has now 2,355 centres of activity, spends about £134,000 a year, and deals with some 40,000 cases. In its report of the work of the forty-fifth year of its existence a statement by the medical officer, Dr. L. D. Saunders, is included. From this it appears that parents and others approach the society for advice as to methods of cure for ailing children; that persuasion is undertaken in the case of children observed by inspectors to need treatment, especially in orthopaedic cases; that ambulances are used for conveying patients to hospital; and that after-care and assistance are given in cases where they are needed. Thus the health of a number of children is always under the charge of the society. The report emphasizes the view that it is better that a child should continue to live in its own home; but instances are recorded in which the brutality of parents compelled the removal of children to better surroundings. It is noted that last year the proportion of cases of ill-treatment reported by the general public—64.2 per cent.—was the highest on record.

A HYGIENIC LECTURE BOARD.

A [illegible] Square, Manchester). This board consists essentially of rollers, by means of which fresh surfaces of white paper can be exposed in a frame. Black or coloured crayons are used for writing on the paper against a wooden background, and as one surface is used up it can be rolled upwards, downwards, or from side to side, as may be required. Special diagrams or other matter can be printed and attached to the paper when necessary. At the completion of a lecture the illustrations on the board can be rolled up and be preserved until required again. The lecture board can be illuminated by means of an electric bulb or reflector, and a simple spring brake mechanism keeps the paper taut. The whole apparatus can be fixed to the wall or placed on the usual easel. The value of this invention from the hygienic and also the labour-saving point of view is obvious.

GOLDEN SQUARE THROAT, NOSE AND EAR HOSPITAL.

MR. F. P. CARROLL, secretary-superintendent of this institution, writes: In the *British Medical Journal* of August 31st (p. 419) this hospital is mentioned among the institutions dealing with disorders of the throat, nose, and ear. May I, however, point out that we have recently opened a number of private rooms for patients making a payment towards the cost of their treatment and maintenance, and that the number of beds in the hospital is now 95, not 75, as stated in the *Journal*. Incidentally, I may mention that the hospital has now been incorporated, and that its new title is the Golden Square Throat, Nose and Ear Hospital

APPOINTMENT OF TUBERCULOSIS MEDICAL OFFICERS IN WALES.

DR. D. A. POWELL (Principal Medical Officer, King Edward VII National Memorial Association, Cardiff) writes: In the Educational Number of the *Journal* (August 31st, p. 428) it was stated that "in England and Wales such [tuberculosis] officers are appointed by [illegible] igh councils," etc. May I draw [illegible] Wales tuberculosis work is carri[illegible], under the aegis of the Welsh [illegible] upon which the seventeen co[illegible] resented, and that the appointment of tuberculosis officers, etc., is vested in the Memorial Association?

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52, 53, and 54.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 151.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

226. Food Allergy.

CITING the views of various authorities as to the possibilities of inducing anaphylaxis by alimentary ingestion, A. STERLING (*Med. Journ. and Record*, June 5th, 1929, p. 612) reports four cases in evidence of this. The symptoms of sensitization to food substances may be gastro-intestinal, respiratory, cutaneous, ophthalmic, or genito-urinary. Gastro-intestinal symptoms may be local, such as swelling of the lips and tongue, or general, such as vomiting, abdominal pain, and diarrhoea. The most important respiratory symptoms are nasal obstruction and hydrorrhoea, with or without attacks of sneezing, and bronchial asthma. The chief cutaneous symptoms are pruritus, urticaria, eczema, angio-neurotic oedema, and erythema; these disturbances may be local or general. Attacks of scleritis and conjunctivitis, and such genito-urinary symptoms as bladder pain, have also been reported. In diagnosis two methods may be used—namely, elimination and cutaneous or intracutaneous tests. It is necessary to ascertain if the sensitivity is due to the handling of foods, or to eating raw or cooked foods. A positive reaction alone is not sufficient evidence of food allergy; food proteins which give such a reaction must be proved to produce the disease. Treatment consists either in eliminating the offending foods from the diet, or in desensitization. The latter may be accomplished by supplying gradually increasing amounts of the obnoxious proteins until the patient develops a certain tolerance, the initial dose being so small that no symptoms occur. Capsules containing powdered food proteins may be given, commencing with a dose of less than 10 mg. three times a day. The problems of food allergy are very intricate, and a careful history and special study of the food intake should be made. In cases of infantile eczema, asthma, and gastro-intestinal disturbances, milk should be removed, temporarily at least, from the diet. The infant should be tested for reaction to foods eaten by the mother, in addition to the general routine testing for such causes as pollen.

227. The Ventricular Rate in Auricular Fibrillation.

E. P. BOAS (*Amer. Heart Journ.*, June, 1929, p. 489) has investigated the changes of ventricular rate in fibrillating hearts over periods of fourteen to twenty-four hours by means of his cardiotachometer, which records and counts the ventricular systoles electrically. He prefaces his results with a summary of our knowledge concerning the mechanism of ventricular slowing in fibrillation; this, whether it is produced reflexly by pressure on the vagus or by the administration of digitalis, must be a result of increased resistance in the conducting system brought about by alterations in activity of the vagus and accelerator inosculations at the auriculo-ventricular node. The author has shown by the cardiotachometer that the ventricular rate is very variable in fibrillation, accelerating with the least emotion or exertion and falling during rest and sleep. These responses are greater than those occurring with normal rhythm, and are observed in many patients even after digitalization. Patients with auricular fibrillation are classified into two groups: the first are highly strung and nervous subjects whose ventricular rates tend to be rapid and who require quantities of digitalis in excess of those indicated by body weight to keep their ventricular action slow and stable; the second group comprises those patients whose rhythms, though irregular, are stable, who do not show an exaggerated response to physical and emotional stimuli, and who are readily controlled by normal digitalis therapy. The essential difference between these two classes of patients is in the vagus-accelerator mechanism, which is hyper-irritable in the first group; this explains the better results obtained when sedatives are administered to such patients in addition to digitalis.

228. Immunization against Diphtheria.

IN 1923 Ramon described a preparation of diphtheria toxin modified by the addition of 3 to 4 per cent. of commercial formaldehyde, followed by incubation at 38° to 40° C. for four to six weeks; he recommended three doses: an initial one of 0.5 c.cm., followed in three weeks by a second of 1 c.cm., and, fifteen days later, by the third dose of 1 to 1.5 c.cm. This preparation is known as diphtheria anatoxin (Ramon) or diphtheria toxoid. G. F. DICK and GLADYS H. DICK (*Journ. Amer. Med. Assoc.*, June 8th, 1929, p. 1901) found that diphtheria toxoid, as prepared by Ramon and given in the doses recommended, immunized 94 of 100 suspected persons to the point of a negative Schick test, while five doses of toxin-antitoxin mixtures immunized 82 out of 100 individuals. They therefore conclude that diphtheria toxoid is a better immunizing agent than the toxin-antitoxin mixture, and may be safely employed in immunizing adults. An extra skin test to detect sensitization to the bacterial proteins in diphtheria toxoid is not necessary. If there is a marked pseudo reaction in the Schick test or a history of diphtheria, it is advisable to give preliminary doses of from 0.1 to 0.25 c.cm. of toxoid. Care should be taken that in the broth employed in producing the toxoid there is not an excessive amount of protein. As it does not contain any foreign serum in the form of antitoxin, the toxoid does not sensitize to horse or other serum.

229. Staphylococcal Septicaemia.

J. ROSENFELD (*Thèse de Paris*, 1929, No. 90) states that all authorities are agreed as to the gravity of staphylococcal infection, almost all forms of which except the hyperacute may give rise to a variety of secondary localization of which endocarditis is by far the most serious, while cutaneous and osseous sequels are most frequent and characteristic. The diagnosis is readily made when there is an obvious portal of entry, but in its absence is difficult unless secondary localizations appear. In such cases the diagnosis can only be made by blood culture, and even then the possibility of contamination must be excluded and the examination be carried out under rigorously aseptic conditions. One of the most serious localizations of staphylococcal septicaemia is involvement of the meninges, as, apart from a case recently seen by the author in a woman aged 30, no recovery has ever been recorded. This fortunately rare sequel may appear at a very late stage of the disease or be apparently a primary affection without any visible portal of entry. Clinically, it assumes the form of cerebro-spinal meningitis, from which it can only be distinguished by bacteriological examination. As a general rule the organism is *Staphylococcus aureus*, though *S. albus* has also been found. The course of the disease is usually rapidly fatal. In exceptional cases it assumes a subacute form, and various localizations may appear and a cachexia develop. Recovery, however, may ensue, as in the author's case, in which the development of spondylitis appeared to limit the infection. In staphylococcal septicaemia, and particularly its meningeal form, active treatment is necessary. In the author's case a cure was effected by a lysat vaccine given daily, first intravenously and then subcutaneously, accompanied by protein therapy (fixation abscess and injection of milk) and chemotherapy. Other measures may also be adopted, especially the intravenous injection of trypaflavine, bacteriophage treatment, and immune transfusion.

230. Etiology of Pulmonary Abscess.

J. HARKAVY (*Arch. Int. Med.*, June, 1929, p. 767) discusses the pathogenesis of abscess of the lung caused by aspiration, and its possible relation to abscess of the lung following tonsillectomy. Both experimentally and clinically experience seems to show that while embolic abscesses may occur they are exceptional; aspiration appears to be the more probable mode of production of lung suppuration following operations on the upper respiratory tract. Through the bronchoscope 27 dogs received 0.5 c.cm. of mixed cultures of bacteria obtained from the sputum of patients suffering from abscesses of the lung following tonsillectomy. Three of these dogs developed abscesses with cavities, in one pulmonary suppuration followed, and a fifth showed a healed suppurative process in the lower left lobe. Aschner reports having found bronchiectatic suppuration, extrabronchial abscess, and suppurative pneumonitis in lungs examined from two to five years after tonsillectomy. Assuming that the results in dogs may be considered as comparable with those occurring in man, Harkavy suggests that aspiration of infectious material from the upper respiratory tract may give rise to pneumonitis followed by necrosis and cavity formation, either becoming healed or persisting with the formation of secondary bronchiectasis.

231. Accidental Infection with Syphilis.

G. MESTCHERSKY and J. OLESSOFF (*Urol. and Cutan. Rev.*, June, 1929, p. 382), who record five illustrative cases, state that over 600 instances have been reported of physicians who have acquired syphilitic lesions in the course of dealing

with patients suffering from the disease. While the general practitioner is often infected in this manner, the list of those so infected in order of frequency is as follows: (1) obstetricians; (2) gynaecologists; (3) surgeons; and (4) syphilologists. Syphilologists come last on the list because, as Fournier points out, they are the most careful. Apart from many inevitable accidents, the acquisition of syphilis by physicians is mainly due to ignorance or the lack of proper precautions. The author recommends that the following preventive steps should be taken: (1) The physician should endeavour to become thoroughly acquainted with all the external manifestations of syphilis. (2) Rubber gloves should be worn in all manipulations, especially during obstetrical or gynaecological examinations. (3) In examining the mouth, larynx, and pharynx, especially in children, the physician should protect the examining hand and cover his face with a mask. (4) The patient should be carefully examined for any signs of syphilis before surgical operations. (5) The physician should always bear in mind the possibility of syphilitic infection in the course of his professional duties.

232. Tuberculous Pleurisy and Thrombopenia.

L. PATERNI (*Il Policlinico*, Sez. Prat., May 6th, 1929, p. 621) reports a case of tuberculous pleurisy associated with purpura and diminution of platelets. A child, aged 12, suffered from cough and fever with slight pleural effusion, epistaxis, and purpura which was generally distributed. By paracentesis 200 c.cm. of blood-stained fluid was removed, and eventually absorption took place. Coagulation of the blood started after twenty minutes, and was complete in half an hour; the serum did not separate until twenty-four hours, and the ligature test was strongly positive. There was no family history of tuberculosis, but the author believes that this was clearly a tuberculous pleurisy, and draws attention to the comparative frequency of purpura in the early stages of tuberculosis. The platelets were markedly reduced during the illness, but when the child left the hospital they had returned towards the normal.

233. Spontaneous Subarachnoid Haemorrhage.

O. ROMCKE and H. J. USTVEDT (*Norsk Mag. f. Laegevid.*, June, 1929, p. 441) record 27 cases of this condition in patients aged from 12 to 73, who were treated in the Ulleval Hospital at Oslo during the period 1918 to 1928. The diagnosis was either made by lumbar puncture or was not established until the necropsy. Seventeen patients recovered and ten died. Among the rarer symptoms observed was glycosuria, which was seen in five cases. In one instance it was associated with acidosis, although no further signs of diabetes developed, and the amount of blood sugar remained normal after administration of glucose. Transient massive albuminuria was observed as well as hypertonus and transient polyuria. In one instance death followed immediately after lumbar puncture, and in two others death occurred spontaneously from respiratory paralysis.

Surgery.

234. Association of Active Tuberculosis and Cancer.

E. P. K. FENGER and C. K. PETTER (*Minnesota Med.*, May, 1929, p. 271), who a year ago reported two cases of associated cancer and active tuberculosis, now publish six more cases, and state that they have found records of many others. They remark that although the general opinion is that this association is rare, there is no proof of antagonism between the two conditions; on the other hand, it cannot be shown that one disease favours the development of the other, with the one exception of lupus, which does increase the tendency to occurrence of epithelioma. Age incidence is an important factor in rendering infrequent the coexistence of tuberculosis and cancer. Tuberculosis is found usually in early and middle life; the majority of deaths (10 to 90 per cent.) from this disease occur before the fiftieth year, while the average age at death from cancer is 60. Another reason for this relatively rare association is that the organs most frequently attacked by cancer—namely, the breast, uterus, prostate, mouth, lower lip, oesophagus, and stomach—are seldom infected with tuberculosis. The authors suggest that pathologists when looking for one lesion tend to overlook another; for instance, enlarged lymph nodes in the vicinity of a carcinoma may be regarded as metastatic until examination of sections shows that they are tuberculous. The authors' series of eight cases is as follows: (1) carcinoma of maxilla and pulmonary tuberculosis; (2) epithelioma of both cheeks and pulmonary tuberculosis; (3) carcinoma of a bronchus and pulmonary tuberculosis; (4) adeno-carcinoma of breast and pulmonary tuberculosis; (5) basal-cell carcinoma of cheek and tuberculosis of fascia over chest wall; (6) melano-sarcoma of intestine and pulmonary tuberculosis; (7) adeno-carcinoma of sigmoid and pulmonary tuberculosis; (8) adeno-carcinoma of stomach and pulmonary tuberculosis. This last case falls into the group of combined lesions in the same organ. Sections of the gastric adeno-carcinoma showed also very definite tuberculosis. Other writers have recorded 61 cases of the combined lesion in the same organ. These cases are exclusive of 173 reported cases of coexistent lupus and cancer. The present authors conclude that (1) cancer and tuberculosis may occur in the same patient and, less frequently, in the same organ; (2) lupus is the only form of tuberculosis which predisposes to epithelioma; (3) cancer definitely develops at the site of chronic irritation, and tuberculous scar tissue appears to favour neoplastic growth, as it is the site of irritation and also of weakened resistance; (4) the two lesions might coexist more often were it not that organs frequently invaded by one are not attacked by the other; the average age incidence of cancer occurs after the large percentage of patients with tuberculosis have died. It has been suggested that tuberculosis, producing necrosis and connective tissue proliferation, favours the implantation of metastatic tumour cells. This is certainly true in pulmonary lesions, but in gastro-intestinal cases the sequence of events is doubtful.

235. Treatment of Varicose Veins.

H. O. MCPHEETERS (*Surg., Gynecol. and Obstet.*, June, 1929, p. 819) compares the advantages of the injection and operative methods of treating varicose veins in the lower extremities. Since the blood flow, especially in the larger varices, is stationary or reversed, obliteration of the dilated varices with their reverse flow must be aimed at. Although there is the theoretical possibility of emboli developing, this is found to be extremely rare clinically; such results of technical error as sloughs and periphlebitis can be entirely avoided, and a perfect result can be obtained if the injection method is continued until all the veins have been obliterated. The mortality rate from pulmonary embolus following the operative method is 0.53 per cent., as compared with 0.00754 per cent. after the injection treatment, or approximately seventy times greater. The non-fatal cases of pulmonary emboli are almost negligible after the injection treatment as compared with their frequent occurrence after operation. The advantages of the injection treatment are that general anaesthesia is not required and that there is no necessity to stay in bed; while operation cases require an average of 15.1 days in hospital and of 34.8 days away from work, under the injection method no hospitalization is needed and patients can continue their daily routine. Recurrence after thorough injection treatment is much rarer than after operation because the sclerosing fluid can spread through collateral superficial veins which could not be easily excised. The statistical data of the operative results were obtained through a questionary sent to a thousand prominent American surgeons; those bearing upon the injection treatment are derived from the author's series of 53,000 previously published cases.

236. Agranulocytosis, with Recovery.

W. B. BLANTON (*Journ. Amer. Med. Assoc.*, June 22nd, 1929, p. 2039) states that agranulocytosis is an uncommon condition, although more than fifty cases have been reported since Schultz first described it in 1922. Its principal manifestations are a bleeding ulcer of the mouth with a membrane simulating diphtheria, enlargement of the liver and spleen, occasional swelling of the inguinal lymphatic glands, ecchymosis, and herpes. The blood count shows a marked leucopenia, often less than 1,000 cells being present. The polymorphonuclears are affected, their number falling to 1 or 2 per cent. More than 90 per cent. of the cases were fatal. Blanton records a case, in a man aged 60, in which recovery ensued, although the white cells numbered only 1,000 and the polymorphonuclears were only 4 per cent.

237. Congenital Hypertrophic Pyloric Stenosis.

E. PERRIN (*Lyon Chir.*, March–April, 1929, p. 204) reports a case of hypertrophic stenosis of the pylorus in an infant, which was successfully treated by the operation of Frédet. Out of five cases so treated two patients made a good recovery, but three died within forty-eight hours of the operation, two apparently from shock, since necropsy revealed no other cause, and the third from haemorrhage from the incision in the pyloric tumour. To avoid this danger Perrin emphasizes the importance of a very careful haemostasis being made. He prefers to under-run the bleeding points with a suture, it being essential that no such points should be neglected. The wounding of the mucous membrane is easily avoided if the muscular fibres are carefully separated with a blunt dissector; the incision must not be deep. The operation need not occupy more than ten

minutes or a quarter of an hour, and is very simple, the death of the three patients being attributed in a large degree to the fact that surgical intervention was not sought early enough, and the infants were, owing to delay, in a poor condition to stand the shock of an operation. It is pointed out, however, that, as congenital stenosis of the pylorus may recover spontaneously, care must be taken not to operate too soon.

238. Arthritis of the Hip-joint in Enteric Fever.

RACHEL KESSEL (*Thèse de Paris*, 1929, No. 148) states that osteo-arthritis is a rare complication of enteric fever, as she has been able to collect only eighteen cases, one of which came under her own observation. In every instance in which bacteriological examination was made *B. typhosus* was the causal organism, except in her own case, which was due to *B. paratyphosus* B. The clinical signs are the same as those of ordinary acute arthritis. The complication usually occurs in the fourth week of the disease. In only one instance was there formation of pus in which the typhoid bacillus was found. The prognosis is favourable, as none of the 18 cases proved fatal, as compared with a mortality of 30 to 50 per cent. in ordinary acute osteo-arthritis of the hip. Care should be taken to prevent the occurrence of dislocation, by the early application of a plaster apparatus, which should not be allowed to remain on longer than six weeks or two months, so as to avoid ankylosis.

Therapeutics.

239. The Action of Digitalis in Complete Heart-block.

S. P. SCHWARTZ (*Amer. Heart Journ.*, April, 1929, p. 408) finds that the utility of digitalis in cases of complete heart-block has not been fully determined. While some authors have described successes, others found that digitalis produced grave or even fatal arrhythmia. Hence competent observers have advised that digitalis should be avoided in any case with bradycardia. Such over-caution, Schwartz thinks, may deprive a patient with complete heart-block of the only remedy that will relieve distress when heart failure occurs. The discrepancy between these views appears to centre on the question whether digitalis relieves by increasing muscular contraction, or by augmenting the automatic ventricular rate. Some hold that acceleration of the slow idio-ventricular rate is a desirable therapeutic result. Others claim that a clinical improvement in cases of complete heart-block, with decompensation, occurs only after an increase of the idio-ventricular rate has been obtained. Schwartz has observed eight patients during the last two years who had complete heart-block and signs of heart failure, and who were treated with tincture of digitalis. He concludes that the ventricular rate is increased appreciably only after administration of very large doses of digitalis; in two instances increase in the ventricular rate was accompanied by dyspnœa and syncope, but these symptoms disappeared when the dominant idio-ventricular rate and rhythm were restored. In two of these patients digitalis initiated transient auricular fibrillation. The author reviews three cases recorded by other observers, and describes three of his own cases in detail. His conclusions are as follows. (1) Digitalis in therapeutic doses may greatly benefit patients with complete heart-block and heart failure. In these cases the improvement is due to the direct action of digitalis on the heart muscle and not to an acceleration of the automatic ventricular beat. (2) In three patients with complete heart-block the ventricular rate was increased appreciably only after administration of very large doses of digitalis. (3) The increase of the ventricular rate in complete heart-block during the administration of digitalis is a toxic symptom, and indicates the necessity for the complete cessation of digitalis administration. (4) Transient auricular fibrillation is another symptom of digitalis intoxication in complete heart-block. (5) Since it is difficult to appreciate the various types of toxic rhythms that occur in complete heart-block during digitalis treatment, it is advisable to prescribe the drug in such cases under careful control by cardiography.

240. Saline Irrigations in Gonorrhœa.

IMPRESSED by Almroth Wright's saline treatment of war wounds, and fearing that astringents such as potassium permanganate might close the mouths of crypts in the urethra and shut off infected areas from contact with the irrigating solution, L. B. CLARKE (*Journ. Roy. Army Med. Corps*, June, 1929, p. 436) has tried 1 per cent. saline solution, and contrasts it with 1 in 10,000 permanganate, to which, he states, nearly every worker has returned for routine treatment. His cases, occurring in Burma, were nearly always severe. In fourteen months he had records of 60 cases, half treated with permanganate, and the 30 cases in which simple saline solution was used. All the patients were kept in bed for fourteen days, and had plenty of barley water, while purgatives and alkaline mixtures were administered equally to both groups. Thirty acute cases were cured under saline in 1,321 days, and two relapses in this group in 57 days. Thirty quite similar cases under permanganate required 1,828 days for their cure, and 8 relapses in this group needed 476 days. The balance in favour of saline treatment was 17 days for each acute case (or 31 days if relapses are included), while the individual cost of treatment with cooking salt was 1s. 6d. Though the numbers treated were few, Clarke concludes that such saline solution is excellent for posterior irrigation, showing many advantages over a 1 in 10,000 solution of potassium permanganate.

241. Transfusions of Unmodified Blood.

A. W. BLAIN (*Annals of Surgery*, June, 1929, p. 917) gives his views on the value of blood transfusions as observed in 3,000 cases. He considers that it has appreciably reduced post-operative mortality and morbidity, and made a successful operation possible in otherwise inoperable cases. In cases of secondary anæmia, deranged metabolism, and unstable biochemical equilibrium, one or more blood transfusions before an operation wholly or partially restore the proper physiological balance. In cases of ruptured tubal pregnancy, in infection with anæmia, in cases of haemolytic streptococcal septicæmia and in secondary anæmia, blood transfusion has been of great advantage. Transfusions for sudden and severe haemorrhage should be given as soon as possible, and the amount of blood be approximately equivalent to the loss. The blood should not be modified in any way, no anti-coagulant being used; citrated blood is not equal in value to whole blood. The blood should not be exposed to the air. Blain considers the Brines apparatus to be the most satisfactory, only about five minutes being necessary for the actual transfusion. The donor and patient should be in the same group when more than 1,000 c.cm. of blood are to be transfused, but in about a third of the cases under review they were not in the same group. Fewer and less severe reactions have followed transfusion from Group 4 to Group 2 than in any other combination. The commonest reason for transfusion was a red blood count of less than 3½ millions before operation. Universal donors can be safely used.

242. Potassium Permanganate in the Treatment of Pneumonia.

J. L. CHESTER (*Ann. Int. Med.*, May, 1929) reports a series of cases of influenza, lobar pneumonia, and broncho-pneumonia treated by potassium permanganate administered as retained enemas. He believes that the infections were cut short, the symptoms rapidly abolished, and the death rate lowered to a marked extent by this method. In his first series of cases Chester gave 3 to 5 ounces of a standardized solution at intervals of three or four hours, for a period of six to ten days. In twenty other cases of pneumonia of a severe type and complicated by chronic heart disease, syphilis, or chronic alcoholism, ten were treated by other methods with fatal results; the remaining ten, who received potassium permanganate, gave 50 per cent. recoveries. Chester refers to the literature on the subject, with special reference to the articles of Nott (*Journal*, March 7th, 1925, p. 443) and Roche (*Journal*, March 12th, 1927, p. 459). Chester urges the importance of further investigation of what appears to be a most promising form of treatment.

243. Suprarenal Cortical Extract in Addison's Disease.

J. M. ROGOFF and G. N. STEWART (*Journ. Amer. Med. Assoc.*, May 11th, 1929, p. 1569) report seven cases of Addison's disease and other less severe forms of suprarenal insufficiency which were treated successfully with an extract prepared from the cortex of the suprarenal gland. To distinguish the cortical hormone from that in the medullary product they use the term "interrenalin," which indicates its origin from the inter-renal tissue of the gland. They administered the preparation in capsules coated to resist gastric digestion, and expect to obtain even better results when more concentrated products can be prepared and investigations have determined the appropriate dosage and the best methods of administration. In animal experiments interrenalin was administered intravenously with good results. In one patient, a man aged 48, who had undoubted Addison's disease, with the usual symptoms, the administration of interrenalin brought about a rapid improvement in the strength and appetite which was associated with reduction of the vomiting. After seven months the nausea had completely disappeared, and the patient, who had previously been confined to bed, was able to sit up for as long as eight hours without being weary. He was subsequently able to walk about and the appetite continued good; moreover, the colour of the skin appeared to be getting lighter.

241. Ergotamine Tartrate in Urticaria.

SUCCESS obtained by the use of ergotamine in the treatment of a woman with Graves's disease, severe urticaria, and dermatographia encouraged BABALIAN (*Bull. Soc. Française de Derm. et de Syph.*, April, 1929, p. 402) to treat eleven cases of urticaria with the same drug. Rothlin showed that this alkaloid acted by paralysing the accelerator and inhibitory sympathetic fibres, and thus was antagonistic in action to adrenaline and ephedrine; it therefore seemed reasonable to try it in sympathoticotonic conditions. Of Babalian's eleven cases treated, four, of from two to six months' duration, were cured, two patients being young men with signs of mild hyperthyroidism and tachycardia, one a man with hyperthyroid signs and definite exophthalmos, and the fourth an elderly man with hypertension and aortic disease, who showed a fall in pulse rate on pressure being applied to the eyeball (positive oculo-cardiac reflex). With the exception of this last case all were clearly sympathoticotonic. In a fifth case cure was incomplete; a young woman who had had attacks of urticaria almost daily for three years did not benefit from ergotamine by the mouth. When daily injections of 1/4 mg. were given she showed some improvement, but they were discontinued because of the supposed risk, and the trouble recurred. Of the four failures, one was in a case of urticaria complicated by asthma; treatment caused exacerbation of the asthma, and was discontinued after eight days. In another patient a positive oculo-cardiac reflex was noted; in the third the urticaria was associated with calculous nephritis; and in the fourth it followed hysterectomy. In the two remaining cases clinical examination revealed no appreciable lesion. The dose of ergotamine tartrate was 2 to 3 mg. by the mouth daily, continued for two to three weeks; this dose was not followed in any case by headaches or painful cramps or nausea. Babalian adds that, excluding cases where bacteria or parasites form an irritative focus, urticaria is either of vagotonic or sympathoticotonic origin; the latter group alone might be expected to benefit from ergotamine. Cases showing a positive oculo-cardiac reflex were of the vagotonic group.

235. The Employment of Blister Serum in Infectious Diseases.

MODINOS (*Paris Méd.*, April 13th, 1929, p. 349) reports that for the last twenty-one years he has employed blister fluid in the treatment of various infectious diseases, such as typhoid and paratyphoid fevers, influenza, rheumatic fever, gonorrhœa, and typhus, with excellent results; his example has been followed by numerous French and Italian clinicians. He states that the advantages of blister fluid over blood serum are, *first, that it is easier to obtain, and secondly, that the bactericidal power of exudations rich in polymorphonuclear leucocytes is always superior to that of the corresponding blood serum*, the average number of leucocytes contained in the serous fluid of a blister being 50,000 per cubic millimetre, of which 70 per cent. are polymorphonuclears. The author's experience of the prophylactic value of blister fluid is limited to two diseases—*namely, measles and influenza, in which the* results have been excellent; but he suggests that blister fluid might be applied in the prophylaxis of other diseases as well, especially those supposed to be due to a filterable virus, as in severe epidemics of typhus and dengue.

246. The Therapeutic Value of Histamine.

S. KATZENELBOGEN (*Journ. Amer. Med. Assoc.*, April 13th, 1929, p. 1240) suggests that the administration of histamine may prove to be useful in two types of non-diabetic acidosis—as, for example, in post-operative acidosis, and in the acidosis which may occur in pregnancy and mental disorders, when the blood sugar level is normal. In view of the assumption that histamine increases the alkali reserve of the blood by draining off its acidity into the stomach, he thinks that the combination of this treatment with concomitant elimination of the hyperacidity of the gastric contents by lavage or neutralization with alkali is to be recommended. He describes some experimental studies in support of these conclusions.

237. Auto-haemotherapy in Gastric Ulcer.

M. CERF (*Bruxelles-Médical*, May, 1929, p. 827), after briefly referring to some of the many hypotheses put forward to explain the occurrence of gastric ulcer, draws attention to a form of protein therapy—namely, auto-haemotherapy—which he says he has found useful. The most marked effect of this treatment appeared to be the reduction of pain, and it is therefore especially recommended for cases in which pain is a prominent symptom, and where there is no marked alimentary stasis or serious distortion of the gastro-duodenal radiographic picture. It is held to be contraindicated when there is manifest deficiency in hepatic function.

Dermatology.

243. Pathogenesis and Treatment of Psoriasis.

PSORIASIS is characterized by abnormal keratinization. According to E. PULAY (*Deut. med. Woch.*, July 12th, 1929, p. 1175) disturbance of the cell chemistry, and particularly the ferment activity of the epidermal cells, prevents the normal disintegration of their nuclei. It has long been observed that psoriasis often tends to occur in families; for this reason, and because a case came to his notice of an individual in whose family several independent cases of diabetes and psoriasis were recorded and in whom the two were combined, Pulay considered it likely that some general disturbance of metabolism might be the cause of the disordered epidermal cell function. Investigating carbohydrate metabolism, he found hyperglycæmia in 50 per cent. and hypoglycæmia in only a few of his cases of psoriasis. Low sugar tolerance indicated a probably imperfect function of the pancreas. Though gout (implying disordered uric acid metabolism) and psoriasis are stated in the literature to be frequently associated, Pulay was unable to confirm this from his own cases. He emphasizes the importance of the metabolism of the inorganic ions of the blood as influencing the fermentative and physico-chemical behaviour of various cells (including those of the skin) directly and through the endocrine system. In 60 per cent. of his cases the blood calcium content was abnormal and in a large number the potassium content was increased. Though endocrine function has been extensively studied in psoriasis by numerous workers, and the thyroid and other glands have at different times been found deficient, no constant association between the disease and a particular type of endocrine constitution or abnormal function of any one gland has been established. Pulay has, however, reported that inadequate ferment (trypsin) secretion by the pancreas is comparatively common; he considers that this is one of the causes of the imperfect disintegration of keratinized cells found in psoriasis. When both the internal and external secretion of the pancreas are inadequate diabetes and psoriasis coexist, and in these cases the psoriasis also benefits from insulin. On these lines he suggests that the improvement which follows reduction in protein intake in some cases and carbohydrate intake in others may be explained. "Discussing various other lines of treatment, he emphasizes the point that, in addition to the usual local applications, various different endocrine and metabolic disturbances may have to be dealt with in different cases.

249. Monilia and Psoriasis.

M. WACHOWIAK, G. V. STRYKER, J. MARR, H. BOCK, and M. S. FLEISHER (*Arch. Derm. and Syph.*, May, 1929, p. 713), reporting their final investigations upon the occurrence of monilia in psoriasis and the possible relationship to the disease, are of opinion that such a relationship does exist, though further investigation is needed to place the matter beyond question. While the organism is present in the faeces in from 6 to 10 per cent. of normal persons the percentage may exceed 40 per cent. in those suffering from intestinal disturbances. Though rarely present in the skin of normal persons it may be found in certain types of dermatological conditions, and, though normally absent from the blood, monilia was present in a limited percentage of patients in whom it was considered to be related to the disease. Of 56 patients with psoriasis 86 per cent. showed the presence of monilia in the faeces; 17 per cent. in the blood, and 36 per cent. in skin scrapings. Experiments to ascertain whether psoriatic patients [illegible] to monilia showed that there was [illegible] nsitiveness than in [illegible] e disease. Although no specific [illegible] ganisms and the disease can be [illegible] the following positive facts are [illegible] tionship existing: (1) the frequent finding of monilia in the stools of persons suffering from psoriasis; (2) the presence of the organism in scrapings from the skin in a fair percentage of cases; (3) the continued desquamation resulting from the application of monilia to abraded surfaces in normal persons; (4) the marked clearing of lesions in certain cases of psoriasis following the injection of the vaccine; and (5) the "thinning and paling" of the lesions following such injections.

250. Lichen Planus.

J. R. DRIVER (*Arch. Derm. and Syph.*, April, 1929, p. 620) from a review of the literature and from a study of 17 cases of typical generalized and localized lichen planus recommends *x*-ray treatment of the spine in such cases. Seven patients were treated by the unfiltered method, six by the filtered method, and four by both methods because of a lack of response; 70.6 per cent. of the cases were favourably influenced, and 59 per cent. were completely cured, those with acute generalized lichen planus responding best. The

effect was more uncertain in the chronic conditions, and did not compare with the more constant benefit obtained by direct irradiation. The results in lichen planus of the mouth were also dubious, and the method is only advised, therefore, when other measures have failed. Driver considers that the filtered method gives more promise of success than the unfiltered; by giving smaller doses on two fields only and repeating it if necessary it is simpler and avoids the dangers that may arise from greater dosage over more surfaces. Especially indicated in the acute generalized type of the disease, *x*-ray treatment of the spine appears to be of definite value, and it can be recommended in all types which do not respond to other methods.

251. J. GOUIN and A. BIENVENUE (*Bull. Soc. Française de Derm. et de Syph.*, February, 1929, p. 96) report a case of generalized lichen planus in a child, aged 10, cured by one application of radiotherapy concentrated on the axilla. The interest of the case is said to lie in the fact that the rays were not directed to the nervous centres, spinal cord, or nerves, showing thus that it is not essential for these regions to be dealt with. The authors believe that in their case the application acted as "shock treatment"; they add that it does not exclude treatment directed to the nervous centres, but may be used as an alternative, as in the case of bismuth in syphilis.

Obstetrics and Gynaecology.

252. The Treatment of Leucorrhoea.

F. L. PAYNE (*Amer. Journ. Obstet. and Gynecol.*, June, 1929, p. 841) points out that in most cases of leucorrhoea the disease is of cervical origin. The operation of uterine curetting as a curative measure in this condition is therefore useless and dangerous, inasmuch as the cervical infection may be carried upwards to the uterine body and beyond. According to Payne, infection of the cervix in the nulliparous patient begins as an endocervicitis involving the lowest portion of the cervix. In the lacerated cervix the mucosa on the everted lips is at once exposed to organisms; mucosal hypertrophy with glandular enlargement and hyperactivity ensue, the normal discharge of mucus is increased, and leucorrhoea results. If the gland ducts become obstructed by mucus, Nabothian cysts are formed, while the mere presence of excessive secretion renders treatment by local application extremely unsatisfactory. In cases where the cervix is lacerated, repair must always be effected if the cure is to be lasting. Diathermy has been used with some success in treating cervicitis, particularly in the milder cases, while irradiation in the hands of Curtis of Chicago has proved extremely beneficial in selected cases. Results are given of 171 cases of cervicitis treated in Pennsylvania University Hospital; patients with superficial laceration, erosion, and uncomplicated cervicitis were treated by the cautery. Lacerations, either unilateral or bilateral, were repaired by trachelorrhaphy, while cases of multiple lacerations, hypertrophy, or extensive cervicitis were dealt with by a modified Sturmdorf operation, where, in view of the fact that the infection was usually limited to the lower cervix, the cervical tissue coned out did not stretch so far as the internal os. The results obtained in this series were very satisfactory. Cauterization gave 93 per cent. cures in 70 cases; trachelorrhaphy resulted in 96 per cent. successes in 24 cases; while in 77 instances the modified Sturmdorf operation gave 95 per cent. cures. The delay of cure was longest in those patients treated by cauterization, on account of tissue destruction with resultant sloughing.

253. Correction of Uterine Displacement.

SINCE from the standpoint of comparative anatomy the uterus is an abdominal and not a pelvic organ, R. CONDAMIN (*Lyon Medical*, May 19th, 1929, p. 609) concludes that the frequency of uterine prolapse and of allied subpathological conditions is due to this displacement. The uterine supports readily lose their toxicity. The assumption of the erect posture through the superadded weight of the abdominal organs he considers to be also an etiological factor. Any uterus which is lower than its physiological level, whatever the cause may be, will give rise to pain and functional or sympathetic troubles. The correction of such a condition implies the elevation of the uterus to its normal level and maintaining it there. Condamin advises a course of massage and suitable exercises to tone up the pelvic muscles and uterine ligaments. He then proceeds to pack the posterior fornix with tampons. Each succeeding tampon compresses and raises the previous one and at the same time distends the vagina. The surgeon's index and middle fingers then exert backward pressure on the column of tampons, the patient aiding by compressing the pelvis. This manœuvre may cause two or three tampons to sink down; these are then replaced. Intelligent patients are told to disinfect their hands and repeat this manœuvre two or three times a day, especially after defaecation. It is important that the last tampon should be well within the vagina and not between the labia, where it would cause discomfort. When completely hidden the tampons exert no pressure on the bladder or rectum, but only on the pouch of Douglas. The tampons can be kept in position for several days if impregnated with glycerin and an antiseptic. The sitting posture continually exerts pressure in the right direction when the tampons are in position. Condamin maintains that there is no elevation, however complex, that cannot be achieved by this procedure, which he terms "columnization," and backward pressure. He admits, however, that after such a course of treatment it may be advisable for a patient to have a well-fitting pessary.

254. Primary Carcinoma of the Fallopian Tube.

L. LE BALLE and R. PATAY (*Gynécol. et Obstét.*, April, 1929, p. 286) state that 129 cases of primary cancer of the Fallopian tube have been recorded; they add notes of two cases described by Douay, and report fully a personal case in which the anatomical findings appear to prove the development of carcinoma from malignant transformation of an intratubal papilloma. The smooth-walled tube, enlarged to the size of a walnut, and occluded at the abdominal ostium, when incised after removal at operation gave issue to an ivory-white cauliflower-like tumour, apparently considerably larger than the capacity of the tube as judged previously. Its insertion towards the abdominal extremity of the tube was 15 mm. long, and microscopic study demonstrated a transition from simple papilloma to carcinoma. The patient, a married nulligravida aged 44, had complained for seven months of abundant vaginal discharge, which at first was watery, but later became sticky and was occasionally tinged with blood. The authors state that primary cancer of the tube appears in two-thirds of the cases in women who still menstruate; in about 48 per cent. of cases it develops in the fourth decennium, and in about 30 per cent. in the fifth. At this age purulent salpingitis is as a rule quiescent, so that the appearance of an apyrexial tubal swelling, accompanied by serous or sero-mucous discharge, should awaken suspicion of a tubal carcinoma. This discharge, at first intermittent, but later persistent and intractable, though rarely mixed with blood, is the significant and early symptom of a tubal carcinoma, which for about six to eight months is entirely intratubal in evolution. If curetting and biopsy eliminate a carcinoma of the corpus uteri, the clinical diagnosis of primary cancer of the tube may be made with some confidence. When the growth is no longer intratubal the prognosis is extremely bad. Apart from one case of Vogt's in which the cure had lasted for seven years, the longest survivals after operation have been from sixteen to twenty-four months in some four or five cases. The present authors' patient appeared well sixteen months after her operation.

255. Metrostaxis without Gross Utero-adnexal Pathology.

W. SHAW (*Journ. Obstet. and Gynaecol. of the British Empire*, Spring, 1929, p. 1) discusses the pathological and clinical findings in a series of 200 cases of abnormal uterine bleeding in the absence of gross morbid defects. He points out that irregular uterine haemorrhage can seldom be attributed to acute or chronic endometritis; the acute variety has definite diagnostic signs, and the chronic form is a rarity and is associated with gross pelvic infections, puerperal sepsis, or necrosis of a malignant uterine neoplasm. For irregular bleeding in the absence of gross disease or endometritis Shaw recommends the term "metropathia," acknowledging at the same time that no recognition is thereby given to the association (causative in some cases) of many of the cases with morbid ovarian function. The 200 cases could be subdivided into the following main groups: (1) metropathia haemorrhagica of Schröder; (2) haemorrhage of the epi[illegible]menorrhoeal type; (3) [illegible]ypomenorrhoeal type; (4) haemorrhage [illegible]ype; (5) a group making about a quart[illegible] associated with endometritis, the rest of obscure causation. The second group was the largest (72 cases); the menstrual interval was reduced, usually to twenty-one or fourteen days; loss was excessive on each day of the period, and in the great majority duration of the bleeding was increased. It is concluded that in these cases the ovarian cycle is reduced in time. The patients were usually aged from 40 to 50; pelvic infection was absent and the uterus was symmetrically enlarged. The endometrium was not usually thickened, showed normal cyclical characters, but oedema and intense hyperaemia, especially of the middle zone, were almost constant. Only in seven cases of this group were the ovaries available, and five showed two corpora lutea of corresponding microscopical development. The first group numbered 53 cases, which

were characterized by a thickened, partly hyperplastic, polypoid endometrium with cystically dilated glands and areas of necrosis in the superficial and middle layers, but no typical premenstrual changes; the associated ovarian changes, which *Shaw regards as secondary, were of an* atrophic nature, but unilateral follicular cysts were invariably present, and a recent corpus luteum was almost always absent. The metrorrhagia cases (group 4) numbered eleven; curettings showed normal cyclical changes and enormous endometrial hyperaemia, and, except at the menstrual epoch, areas of disintegration were absent. In the two cases of this group in which the ovaries were obtained they were enlarged, hyperplastic, and hyperaemic.

256. Radium Treatment of Metastases after Hysterectomy for Malignant Disease.

P. BROCQ and H. RUBENS-DUVAL (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, April, 1929, p. 276) describe the case of a woman, aged 42, in whom Wertheim's operation was performed for carcinoma of the cervix. Four and a half years later a small, hard, red ulcerated nodule was found in the vault of the vagina. Tubes containing radium were applied for seven days, one in the substance of the metastasis and one outside it. The antecedent conditions became re-established, and have now remained so for more than six years. The nodule was not submitted to biopsy, which, it was thought, would have made radium-puncture less easy. A. SIREDY (ibid., p. 278) alludes to a patient who is now well five and a half years after radium treatment of a rapidly growing metastasis which appeared on the cervical stump four weeks after hysterectomy had been performed for chorion epithelioma of the uterus following hydatidiform mole. The patient, a woman aged 28, had had an emergency operation for perforation of the fundus uteri by the growth.

Pathology.

257. The Kahn Reaction in the Diagnosis of Syphilis.

MLLE E. SALAMON (*C. R. Soc. de Biologie*, May 31st, 1929, p. 286) has carried out a series of comparative investigations on 759 serums and 205 cerebro-spinal fluids, using the Kahn, Wassermann, and Meinicke tests. In the case of the serums there was complete agreement between the results in 92.7 per cent., and in the case of the spinal fluids in 90.7 per cent. In the discordant group there were thirty serums from patients who on clinical grounds were considered certainly to be suffering from syphilis; of these, 23 gave a positive Kahn reaction, 19 a positive Wassermann, and 20 a positive Meinicke reaction. In the same group there were twenty-five serums from patients who clinically were non-syphilitic; of these, two gave a positive Kahn reaction, 16 a positive Wassermann, and 14 a positive Meinicke reaction. In the discordant group there were 19 spinal fluids; of these, 15 gave a positive Kahn reaction, 17 a positive Wassermann, and 8 a positive Meinicke reaction. Of these fluids all but two were from patients considered certainly to be suffering from syphilis. It would appear, therefore, that the Kahn test is slightly more delicate than either of the other two in definitely syphilitic cases, but that in non-syphilitic cases it gives a much lower proportion of positive reactions. Nevertheless, as both the Wassermann and the Meinicke tests occasionally give positive results when the Kahn test is negative, the author concludes that in the diagnosis of syphilis it is advisable to employ all three tests in parallel.

253. Abortus Fever in Denmark.

M. KRISTENSEN and P. HOLM (*Centralbl. f. Bakt.*, May 28th, 1929, p. 281) between April, 1927, and December, 1928, examined 4,623 specimens of blood from different patients sent in for the Widal reaction; of these, 500 agglutinated *Brucella abortus* in the titre of 1 in 100 or over. In only 0.1 per cent. of about 1,000 control serums examined was the reaction positive to *Br. abortus*, and in these cases the titre *was comparatively low. Examination of a certain number* of patients over a considerable period of time showed that after an attack of undulant fe[illegible] titre gradually fell, till after a year it [illegible] n 100. A positive reaction in a titre of [illegible] atient suffering from clinically undulant fever may therefore be accepted as diagnostic of an active infection, and is not to be explained by the persistence of agglutinins from a previous infection. From 21 of 34 patients examined *Br. abortus* was recovered in pure culture. After a careful study of the properties of these organisms the authors concluded that they were indistinguishable from *abortus* strains isolated from cattle; but that they could be distinguished with a fair degree of certainty from *melitensis* strains, and from *abortus* strains of porcine origin. Epidemiological investigation of the 500 cases of *Br. abortus* fever showed that the disease was commoner in the country than in the town; it attacked most frequently males between 15 and 40 years of age, and had the highest incidence in agricultural workers, especially in those who came into close contact with cattle. It would appear that, though infection may occur by milk; *there is some other method, probably of greater importance;* the authors seem to consider that direct contact with infected animals may be responsible for many human cases. Notes were obtained of pregnancy occurring in three of the patients, and in each patient abortion occurred; in one case *Br. abortus* was recovered from the placenta. It would appear, therefore, that this organism may be responsible for cases of abortion in human beings as well as in cows.

259. Relation of Varicella to Herpes Zoster.

T. M. RIVERS and L. A. ELDRIDGE (*Journ. Exper. Med.*, June, 1929, p. 893) have compared the age incidence and the seasonal distribution of varicella and herpes zoster in New York for the thirteen years 1914-26. They find that varicella occurs chiefly in children under 10 years old, and has a very definite seasonal periodicity, the maximum incidence being from December to June. Herpes zoster, on the other hand, is commonest in the second to the sixth decade of life, and shows no marked seasonal fluctuations. In the authors' opinion this statistical evidence does not support the view that varicella and herpes zoster are caused by the same virus. In another paper (ibid., p. 907) certain experimental observations are recorded. It had previously been found that some species of monkey — *Cercopithecus sabaeus* and *Cerco. lalandi*—showed a limited susceptibility to varicella; that is to say, if the virus was injected into the testicles acidophilic nuclear inclusion bodies became demonstrable on the fifth or sixth day. The appearance of these inclusion bodies was regularly prevented by convalescent varicella serum. In the present series of experiments immune serum from herpes zoster patients was mixed with varicella virus and *inoculated into the testicles of monkeys. Three* experiments were performed, and in two of them the zoster serum failed to prevent the development of the inclusion bodies; in the third there was apparent neutralization of the virus. One of the negative results was rendered very striking by the fact that the serum of the zoster patient's sister, who had subsequently developed chicken-pox, neutralized the varicella virus completely. The authors conclude that in the majority of instances the etiological agents concerned with varicella and herpes zoster are not identical.

260. The Blood in Typhoid Fever.

J. SABRAZÈS and J. MONGIRET (*C. R. Soc. de Biologie*, May 13th, 1929, p. 49) from examination of the blood of eleven ordinary cases and five complicated cases of typhoid fever came to the following conclusions. In ordinary cases there is slight anaemia (an average of 4 million red cells per c.mm. and 80 per cent. haemoglobin) and a leucopenia of 3,000 to 4,000. The blood plates are slightly diminished. There is a *relative lymphocytosis* (40 to 50 per cent.), which lasts until convalescence. Numerous prolymphocytes may be seen. Contrary to what is often stated, the number of large monocytes and of their multilobular forms is little affected, but there is a slight increase in convalescence. The number of polymorphonuclear cells is usually lowered, and there is a well-marked shift to the left; 20 to 30 per cent. of the polymorphonuclears in the uncomplicated forms show basophil inclusion bodies. Eosinophils and mast cells are scanty or absent until convalescence. A large number of degenerated leucocytes may be found even in uncomplicated cases, and are due to plasmolysis, nucleolysis, pyknosis, and caryorrhexis. Türk's cells are also found, with a few histiocytic cells and even large endothelioid cells. Complications such as intestinal haemorrhage, peritonitis, parotitis, and otitis often give rise to leucocytosis and polymorphonuclears.

261. Filterable Forms of Typhoid Bacilli.

P. ARSONNEAU (*Thèse de Paris*, 1929, No. 103) states that the difficulty experienced by several observers, including *himself, in finding* typhoid bacilli in infected water suggests that in a large number of cases infection is effected not by the typhoid bacillus in usual form, but by filterable forms of this bacillus. The existence of these filterable forms is proved to-day, as they may be obtained in the laboratory, as well as in infected water and in the patients' stools. The author records two cases in which these *filterable forms were* found in the blood, and were detected by blood culture. The study of these blood cultures shows that the filterable forms give rise to a special septicaemia which occurs some time before the bacteriaemia. It appears to be a proved fact that when these forms after becoming bacilli are attacked by the bacteriophage they resume their filterable form and are so eliminated in the stools and reach the water again. In some cases these filterable forms do not evolve but give rise to slight constitutional disturbance presenting an ill-defined clinical picture.

Sept. 10th, 1929.

Dear Sirs,

I have prescribed your Agotan* Tablets, grains $7\frac{1}{2}$, to an elderly lady suffering from Rheumatoid Arthritis of the hip and knee joint.

She has derived great benefit from the treatment and her pains have been much relieved.

————————, M.B.

* *This refers to Howards' Agotan Tablets. Agotan is official in "The British Pharmaceutical Codex, 1923."*

According to eminent Medical Men, Agotan owes its remarkable success in the treatment of Gout, Sciatica, Rheumatism, Lumbago, Neuritis, Arthritis, etc., to the very powerful elimination of Uric Acid from the blood, thus preventing its deposition in joints, etc.

Obtainable through any wholesale house in bottles of 25 and 50 Tablets of $7\frac{1}{2}$ grains each, or in Powder.

Samples and full particulars to Medical Men from the manufacturers:

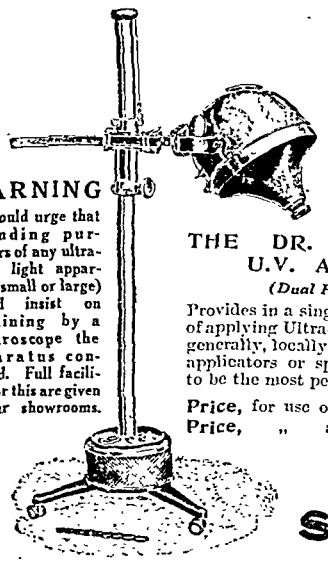
ULTRA-VIOLET LIGHT



WARNING

We would urge that intending purchasers of any ultra-violet light apparatus (small or large) should insist on examining by a spectroscope the apparatus concerned. Full facilities for this are given at our showrooms.

THE types illustrated are but two of our many models which provide at economical cost a highly efficient source of Ultra-Violet Radiation. Widely approved by the Medical Profession on account of their simplicity and dependability, and 100% British.

THE DR. PERCY HALL U.V. APPARATUS

(Dual Purpose Model)

Provides in a single apparatus the means of applying Ultra-Violet Radiation either generally, locally, or internally by quartz applicators or specula. Acknowledged to be the most perfect type yet designed.

Price, for use on direct current - £38
Price, „ alternating „ - £53

THE "MEDISUN U.V." APPARATUS

Quartz Mercury Vapour Type.

Designed for whole body or local applications.
Suitable for general practitioners, or for use in the homes of private patients.

Price, for use on direct current - £12
Price, „ alternating „ - £18
Telescopic Stand, as illustrated, £3 extra

SMOKE AND DISEASE

Smoke is perhaps the gravest danger to our national health.

Statistics show that about fifty per cent. of the time lost in workshops and offices in this country is caused by respiratory diseases due to the pollution of the atmosphere by smoke.

More than half the three-year-olds of this country have rickets, because they are robbed of sunlight by the smoke pall. The amount of sunlight has been found, by readings taken from various parts of England, to be in inverse proportion to the degree of air pollution.

About seven-eighths of the sun's power is shut off by smoke from the centre of London, and eighty tons of poisonous soot are emitted in the capital every hour.

The remedy lies in the burning of the smokeless fuels, gas and gas coke. The atmosphere is not polluted in the slightest degree either during their manufacture or their actual combustion.

GAS *brings health*

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, unequalled, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. *Milk, meat, fruit, and vegetables are supplied* to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at *Llanfairfechan, amidst* the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

NEURASTHENIA
BELVOIR NURSING HOME, ASTON-ON-TRENT, DERBY.

Private Nursing Home for Neurasthenia and allied Functional Nervous Disorders, for general Convalescent Cases, and those requiring Electrical Treatment.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certificate cases are *not* received. *Electrical Treatment*, Radiant Heat, X-ray, Ultra-violet Light, and Massage is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.
Dr. Douglas Morris can be seen by appointment in London.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either *voluntarily or under Certificate. Patients are classified in separate* buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

MAUDSLEY HOSPITAL,
DENMARK HILL, S.E.5.

Telephone: RODNEY 4341.

County Borough and Port of GRIMSBY.

APPOINTMENT OF PART-TIME CLINICAL TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from fully qualified and registered medical men not over 45 years of age for the above post.

Candidates must have had previous Dispensary and Sanatorium experience and have held a Resident post in a general Hospital. They must also possess the D.P.H. and be able to use Ultra-violet and X-ray apparatus. Experience in surgical tuberculosis will be deemed to be an additional qualification.

The appointment is subject to the approval of the Ministry of Health. Salary £750 per annum.

The selected candidate will be required to assist the Medical Officer of Health in his routine duties when not engaged in tuberculosis work.

Form of application and conditions of appointment can be obtained from the undersigned, and should be accompanied by three recent testimonials, to reach me not later than September 30th.

Town Clerk's Office, JOHN W. JACKSON,
170, Victoria Street, Town Clerk.
Grimsby.

County of London.

The London County Council invites applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (man or woman) in its Mental Hospitals Service. Candidates must be under 35 years of age and be registered to practise both in medicine and surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, the present total commencing remuneration being approximately £423 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly) if required to be resident. In the case of women marriage terminates contract of service. Candidate appointed will be pensionable under the Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Tuesday, October 1st. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of ihs career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
Capt.			150	3rd
	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in October to make nominations, and the selected candidates will be required to attend a course of instruction commencing on the 23rd October, 1929.

University of Cape Town.

APPOINTMENT OF ASSISTANT ANATOMIST.

Applications are invited for the post of Assistant Anatomist in the Department of Anatomy at the University of Cape Town.

Candidates must have a registrable medical qualification, and must have had experience of teaching anatomy. The appointment is a whole-time one, and the holder will be expected to take a responsible share in the teaching and to undertake research.

Salary.—£750 per annum, but for pension purposes it will be regarded as being on the scale £500—£25—£650.

Salary will be paid from February 1st, 1930, provided the Assistant has vacated his previous post on or before January 31st, 1930, and reports for duty on or before February 25th, otherwise salary will be paid from date of assumption of duty.

The appointment is for a period of three years in the first instance.

Passage Money.—£50 will be allowed for passage expenses, subject to a proportionate refund in the event of the Assistant terminating his agreement within three years of the date of the assumption of duty.

Duties.—To be assumed on March 1st, 1930.

Applications, stating age, professional qualifications and experience, together with copies of three recent testimonials (all in duplicate), should reach the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2, from whom forms of application and further particulars may be obtained, not later than October 8th, 1929.

University of Sydney.

The Senate invites applications from gentlemen qualified to hold the BOSCH CHAIR OF SURGERY, the duties of which commence on March 1st, 1930. The salary is £2,500 per annum, without Superannuation rights. Applications (8 copies) should reach the undersigned by October 19th, 1929, but the University reserves to itself the right to invite any person to the Chair. A memorandum giving further particulars may be obtained on request.

The Senate invites applications from gentlemen qualified to hold the BOSCH CHAIR OF MEDICINE, the duties of which commence on March 1st, 1930. The salary is £2,500 per annum, without Superannuation rights. Applications (8 copies) should reach the undersigned by October 9th, 1929, but the University reserves to itself the right to invite any person to the Chair. A memorandum giving further particulars may be obtained on request.

The Senate invites applications from gentlemen qualified to hold the BOSCH CHAIR OF BACTERIOLOGY, the duties of which commence on March 1st, 1930. The salary is £1,100 per annum, subject to a deduction of 5 per cent. for the University Professorial Superannuation Scheme. Applications (8 copies) should reach the undersigned by October 19th, 1929. A memorandum giving further particulars may be obtained on request.

AGENT-GENERAL FOR NEW SOUTH WALES, LONDON.
Australia House, Strand, London, W.C.2.

Medical Department,

SUDAN GOVERNMENT.

A MEDICAL OFFICER is required immediately for the Sudan Medical Service. The candidate must be single and should be under 30 years of age, and he must have held a Resident appointment in a large General Hospital.

Pay commences at £E.730 a year, rising to £E.1,200 after thirteen years' service. On confirmation of his appointment, the selected candidate will be eligible for pensionable service.

Applications (in writing only), with copies of recent testimonials, should be made to Dr. HODSON, 24, Welbeck Street, W.1, from whom, and from the Secretaries or Deans of the principal Medical Schools, further particulars can be obtained.

City of London Hospital for DISEASES OF THE HEART AND LUNGS,

Victoria Park, E.2.
('Bus, tram, and rail, Cambridge Heath, L. & N.E. Railway.)

Applications for the post of HOUSE PHYSICIAN (male), with copies of recent testimonials, are invited to be sent to the undersigned by Monday, October 7th.

The appointment will be for six months from November 1st.

Salary at the rate of £100 per annum, with board, residence, and laundry provided.

GEORGE WATTS, Secretary.

Central Health Board,

FEDERATED MALAY STATES.

Applications are invited for Three MEDICAL OFFICERS for the Estate Service of the above Board. Candidates must be of pure British descent, between the ages of 25 and 35 years and must have held the post of House Physician and House Surgeon at a General Hospital. If they have not already taken a course at one of the recognized schools of Tropical Medicine, they will be required to do so before sailing, and an allowance is made for this purpose. Salary is at the rate of $700 per mensem for the first year equivalent to £980 a year, $750 per mensem for the second year equivalent to £1,050 a year, $800 per mensem for the third year equivalent to £1,120 a year. The first term of service being for three years. Free passages are granted to successful candidates and their wives, also their children under 10 years not exceeding the cost of a first-class passage, together with free furnished quarters and an allowance of $140 per mensem to cover the running costs, upkeep and depreciation of a car. ($1 equals 2s. 4d. sterling). At the end of the first term of three years' service, six months' full pay leave, exclusive of allowances, and free passages are granted. There is a provident fund in substitution of a pension fund. Candidates will be required to pass a medical examination before final selection. Further details of the Service will be given on application to the Agent, Malayan Information Agency, Malaya House, 57, Charing Cross, London, S.W.1.

Northamptonshire.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Northamptonshire County Council invite applications for the appointment of Medical Officer of Health and School Medical Officer for the Administrative County of Northampton.

Applicants must be legally qualified and duly registered medical practitioners, and hold a Diploma in Sanitary Science, Public Health, or State Medicine. They must also have had previous experience in Public Health administration under a local government authority.

The salary will be at the rate of £1,100 per annum, payable monthly, together with offices, staff, stationery, and such allowances for travelling and other necessary out-of-pocket expenses as the County Council shall from time to time approve. A periodical review of salaries is made by the County Council and suitable increments of salary will be given for proved ability and satisfactory service.

The salary will be subject to a deduction of 5 per cent. per annum for superannuation in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which the County Council have adopted.

The candidate appointed will be required to pass a medical examination.

The officer appointed must reside at a place to be approved by the County Council and devote the whole of his time to the service of the Council and Education Committee; he will be responsible for the carrying out of the Public Health work now developing upon or which may hereafter devolve upon the County Council or its Committees.

The appointment is to be held subject to the provisions of the Sanitary Officers Order, 1926, and is determinable (subject to the provisions of Section 68(5) of the Housing, Town Planning, etc., Act, 1909), upon three months' notice on either side.

Further particulars, if required, may be obtained on application to the undersigned.

Applications, endorsed "Medical Officer," with not more than three recent testimonials, giving full particulars of the training, qualifications, experience, and age of the applicant, should reach the undersigned on or before Sept. 27th.

Applications and testimonials for the use of members of the Public Health, etc., Committee must be printed or typewritten, and not less than thirty copies should be supplied for this purpose.

Canvassing will disqualify.

H. A. MILLINGTON,
County Hall, Northampton. Clerk to the County Council

Parish of St. John, Hampstead.

The Guardians of the above Parish require a JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER at their New End Hospital to start duties as soon as possible. Appointment six months, renewable at option of the Guardians. Salary £200 per annum, with board, lodging, and washing. Further particulars can be obtained from the Medical Superintendent. Applications to be sent to my office on or before 10 a.m. Thursday, September 26th.

H. WESTBURY PRESTON,
Guardians' Offices, New End, Hampstead, N.W.3. Clerk to the Guardians.

Glamorgan County Council.

APPOINTMENT OF MEDICAL OFFICER.

The Glamorgan Education Committee invite applications for the appointment of a Male Medical Officer. Applicants must have had at least three years' professional experience after qualification, and also hold a Diploma in Public Health. Special experience in Eye Diseases and Refraction work is essential, and experience in Orthopædic work would also be an advantage. Candidates must not be over 35 years of age.

The commencing annual salary will be £632 10s. less 5 per cent., and after three years will be increased to £641 5s., and thereafter by annual increments of £23 15s. to a maximum of £769.

Travelling and subsistence expenses will be paid according to scale.

The post is an established post under the County Superannuation Scheme, and for this purpose a deduction of 5 per cent. of the annual salary will be made, repayable with interest on retirement before pensionable age.

The person appointed will be required to give his whole time to the duties, under the control and supervision of the School Medical Officer, and to reside where directed by the Committee.

The appointment will be terminable by two months' notice on either side.

Applications for the appointment, stating age and qualifications, and accompanied by copies of not more than three recent testimonials, should be sent to the School Medical Officer, Dr. E. COLSTON WILLIAMS, County Hall, Cardiff, and should be received by him not later than the first post on the morning of October 2nd.

Canvassing, personal or otherwise, will be a disqualification.

Glamorgan County Hall, Cardiff. Sept. 14th, 1929. HENRY ROWLAND, Clerk of the County Council.

Metropolitan Borough of LEWISHAM.

ASSISTANT MEDICAL OFFICER OF HEALTH AND MATERNITY AND CHILD WELFARE MEDICAL OFFICER.

The Lewisham Borough Council invite applications from duly qualified medical men for the appointment of Assistant Medical Officer of Health and Maternity and Child Welfare Medical Officer.

The salary will be at the rate of £650 per annum inclusive, rising by annual increments of £25 to £750 per annum inclusive.

The person appointed will be required to give whole-time to the duties of the office, and will be under the administrative control and supervision of the Medical Officer of Health. He will be required to live within the Borough.

The appointment is subject to the approval of the Ministry of Health and to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and also subject to three months' notice on either side to terminate the same.

Preference will be given to candidates (a) who have special experience in Maternity and Child Welfare work, and (b) those holding, in addition to other qualifications, a Diploma in Public Health.

Selected candidates will be required to undergo a medical examination.

Applications for the appointment, accompanied by copies of not more than three recent testimonials, must be made on forms to be obtained from the undersigned, and should be received here not later than 4 p.m. on Monday, September 30th.

Canvassing, directly or indirectly, is prohibited, and will disqualify.

Lewisham Town Hall, Catford, S.E.6. September 7th, 1929. JOHN W. SHUTER, Town Clerk.

City of Coventry.

MEDICAL OFFICER OF HEALTH.

The Coventry City Council invite applications from qualified practitioners in Medicine, Surgery, and Midwifery, who are also holders of a Diploma in Public Health, for the position of Medical Officer of Health of the City.

A form of application (upon which full particulars are given of the conditions of appointment and the duties of the office) may be obtained from the undersigned, and all applications must be made on the prescribed form.

Age must not exceed 40. The salary will be an inclusive salary on Grade A of the Council's scale, commencing at £1,225 and rising to £1,500 in the manner stated in the conditions of appointment. The post will be a designated post under the Local Government and Other Officers Superannuation Act, 1922.

Applications must reach the undersigned not later than Saturday, October 5th.

Canvassing, direct or indirect, will be regarded as a disqualification.

Council House, Coventry. FREDERICK SMITH, Town Clerk.
September 10th, 1929.

Birmingham Union.

SELLY OAK HOSPITAL.

RESIDENT PHYSICIAN (Male).

Applications are invited for the above post, giving age, full details of experience and qualifications and accompanied by copies of not more than three recent testimonials. Applications should be forwarded so as to reach the undersigned not later than Wednesday, October 9th.

Candidates must hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or be a Fellow or a Member of the Royal College of Physicians of London or Edinburgh.

The Resident Medical Staff, including the Medical Superintendent, numbers eight.

The present Hospital accommodation consists of 540 beds for acute cases, divided into general medical, general surgical, gynæcological, obstetrical, and children's sections. Out-patient and Casualty Departments, as well as the following fully equipped special departments, are attached to the Hospital:—Pathological, X-ray, Electro-therapeutic, Massage, Ultra-violet ray.

The admissions and discharges for the year 1928 were 7,284 and 7,448 respectively.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the Medical Superintendent and will carry out such duties as may be assigned to him by such officer with the consent of the Guardians. Should occasion arise, the successful applicant must be prepared to assist at any of the other Institutions in the Union without additional remuneration.

The commencing salary will be fixed between £400 and £600, according to qualifications and experience. If fixed lower than the latter figure, the salary will rise to that figure by £50 annually, subject to satisfactory service. The Guardians' regulations provide that at the expiration of 12 months' satisfactory service additional allowances not exceeding in all £150 per annum are granted to the holders of certain prescribed degrees and/or diplomas.

Furnished quarters, rations, laundry, and attendance, will be provided. A deduction of 2 per cent. will be made from the salary and value of the emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars may be obtained, if desired, on application to the Medical Superintendent, R. P. S. KELMAN, Esq., M.B., F.R.C.S.(Eng. & Edin.).

Union Offices, Edmund Street, Birmingham. C. P. BEECH, Clerk to the Guardians.

Royal Devon & Exeter Hospital,

EXETER.

HONORARY PHYSICIAN.

Applications are invited for the post of Honorary Physician at this Hospital.

Candidates must be Fellows or Members of the Royal College of Physicians of London and Doctors of Medicine of one of the Universities of the United Kingdom and if appointed must practise as a Physician.

Particulars as to duties, etc., may be obtained from the undersigned.

Applications, together with certificates of birth and registration, original testimonials, with 35 copies, should be delivered to the undersigned not later than Saturday, October 26th.

Signed on behalf of the Committee,
S. S. COLE, Secretary.

N.B.—Canvassing of any member of the Standing Elective Committee is forbidden by the Rules of the Hospital.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

An ASSISTANT PATHOLOGIST and RESEARCH FELLOW is required in the Pathological Department on October 3rd.

Gentlemen are invited to send in their applications, addressed to the Secretary, accompanied by copies of not more than three testimonials given specially for the purpose, before 12 o'clock, on Monday, September 30th.

The appointment is whole-time and is non-resident.

The appointment is made for one year, but the successful candidate will be eligible for reappointment.

Salary £450 per annum and allowance for substitute for annual holiday, 24 guineas.

The Assistant Pathologist and Research Fellow will devote half his time to the routine bacteriological and serological work of the Hospital, and the other half to the carrying out of Research work, primarily in connection with Rheumatism. Preference will therefore be given to candidates who have shown their aptitude for Research by their previous experience or publications.

Candidates must be registered medical men, and be prepared to take up the duties on October 3rd.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, October 2nd, at 4.45 p.m.

Forms of application, copy of the rules and details of the duties of the appointment, will be supplied on application to the Secretary.

By Order of the Board of Management,
JAMES McKAY,
September, 1929. Secretary.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on October 4th and 14th respectively.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock, on Monday, September 30th, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, October 2nd, at 4.45 p.m. precisely.

Forms of application and copies of the Rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES McKAY,
September, 1929. Secretary.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele Address: Triform, Wesdo—London. Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Practices and Partnerships for Disposal. Full particulars sent free.

$C_8H_{10}N_4O_2 + H_2O$

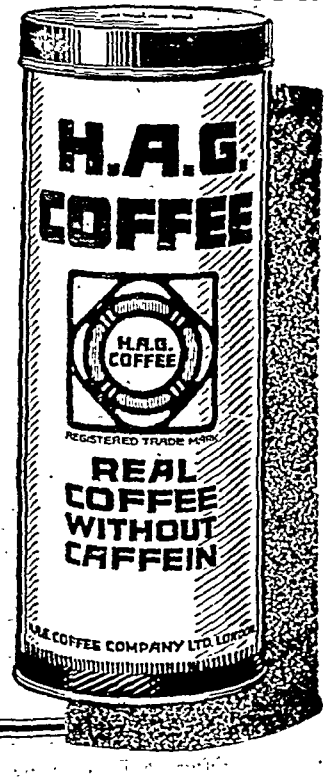
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.

DOCTORS THEMSELVES
PRAISE
"RYVITA CRISPBREAD"

Dr. . . . Baker Street, W.1—"I am already using and prescribing 'RYVITA,' and I think it excellent."

Dr. . . . S.W.1—"This product solves the question—the importance of which has recently been brought into such prominent notice:—viz., of finding a wholemeal bread, pleasant to the taste, and demanding thorough mastication."

Dr. . . . Ledbury.—"Please send 10 lbs. of 'RYVITA.' Everyone prefers the 'RYVITA' to bread. It is far superior from the point of view of health."

Dr. . . . Bournemouth.—"Am delighted with your 'RYVITA.' Please send me a further 7 lbs."

Dr. . . . Yeovil—". . . . I have recommended 'RYVITA' to a large number of my patients, who are highly delighted with it."

Dr. . . . Crewkerne.—". . . Up to now I think I have consumed personally about 30 lbs. of 'RYVITA.' My boys love it; scores of my patients are eating it."

Dr. . . . Glasgow—". . . Many ask about 'RYVITA'; we use nothing else, and always have it on the table for visitors' use as some, like ourselves, are already very fond of it. It is exceptionally good for keeping the gums and teeth in a sound healthy condition. The salivary glands are also stimulated to function in a normal and healthy manner; contributing further to a sound state of oral hygiene. I will be glad to recommend 'RYVITA,' and wish you and your Company every prosperity."

Dr. . . . Dreitwich—"Kindly send me another 10 lbs. It is the very thing I have been looking for, for years. My household like it very much."

. . . . Esq. (Dentist), Wimpole Street, W.—"I shall be pleased to recommend 'RYVITA' to my patients, especially for children's use."

Dr. . . . . Eastbourne.—"Very delicious to eat."

"*Dr. . . . . S.W.1.* has recommended and distributed several packages to patients of supply he purchased last week, and would be glad of samples for this purpose."

Dr. . . . . Almondsbury.—"I am exceedingly pleased with 'RYVITA,' and personally I have been freer from indigestion while taking it than for many months; consequently, I am recommending it freely in my practice. Send me a supply of samples to give to my patients. I have given several patients some of my own stock to start on."

Dr. . . . . Southport.—"Have already induced a number of my patients to use 'RYVITA.' In cases where there has been habitual constipation, the result of eating 'RYVITA' has been excellent and the constipation has yielded without the use of aperients. You cannot make 'RYVITA' too widely known."

(Later letters.)

"I have nothing but good to report regarding 'RYVITA CRISPBREAD.' It has been excellent in all cases of constipation. Send me about 25 booklets, also a sample of 'RYVITA' to patient at address below."

"Some little time ago you brought 'RYVITA' to my notice. I got a large number of my patients to take it regularly. Some of these have been supplied in shops with 'something just as good.' Some are now buying an article which to my mind and experience is not as good as 'RYVITA.' There should not be this risk of their having something else palmed off on the customers."

NOTE.—The originals of all the above letters, are, of course, available, and can be seen by any persons properly interested.

(We could fill many pages with similar letters from Medical Men.)

EATAN
Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 12/- bottles.

Special Terms to Hospitals.

Test sample and literature sent post free on application to:

A TEXTBOOK OF MEDICINE

Edited by J. J. CONYBEARE, M.D.(Oxon.), F.R.C.P., Assistant Physician to Guy's Hospital.

CONTRIBUTORS:—J. J. Conybeare, M.C., M.D., F.R.C.P.; W. H. Craib, M.C., M.B., M.R.C.P.; Geoffrey B. Dowling, M.D., M.R.C.P.; E. H. R. Harries, M.D., D.P.H.; Arthur Maitland-Jones, O.B.E., M.C., M.D., M.R.C.P.; Vernon E. Lloyd, M.C., M.B., B.S.; Hugh MacLean, D.Sc., M.D., F.R.C.P.; Geoffrey Marshall, M.D., F.R.C.P.; Trevor Owen, M.B., M.R.C.P.; F. M R. Walshe, D.Sc., M.D., F.R.C.P.

SOME REVIEWS:

"We feel sure that any student who purchases this book will never regret it, and we would advise anyone who is looking for a concise yet clear textbook of medicine to buy it."
—Manchester University Medical School Gazette.

"The book as it stands is one which can be confidently recommended to students and practitioners. It is clearly printed and it 'opens' well. The phraseology throughout is refreshingly clear; new aphorism and abundant pithy verbal illustrations are supplied and the index is good."—The Lancet.

"We know of no other textbook which the harassed third-year student could read more profitably during his course of medicine lectures."—The Student.

"One cannot help feeling that here is a book of some 950 pages which contain little or nothing that the student can afford to omit—a book to be recommended, especially as its paper, binding, and letterpress are universally excellent."—Middlesex Hospital Journal.

"The book is up-to-date, clearly written and concise, and it should prove of value to the student not only for examination purposes, but as a book of reference."—Post-Graduate Medical Journal.

"The book deserves high praise and can confidently be recommended to students and practitioners who seek a concise, eminently readable and up-to-date work on the essentials of medicine."—Medical Times.

"Considering Conybeare's textbook as a whole, I regard it as the best of its kind for students."
—London Hospital Gazette.

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors.

Edited by

H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond.,
Asst. Phys., St. Thomas's Hospital; Con. Phys., Royal Northern Hosp.

This book is intended to provide an account of the symptomatology of disease. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.

BRITISH MEDICAL JOURNAL:—"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialties, are tersely written and well up to date."

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps, Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

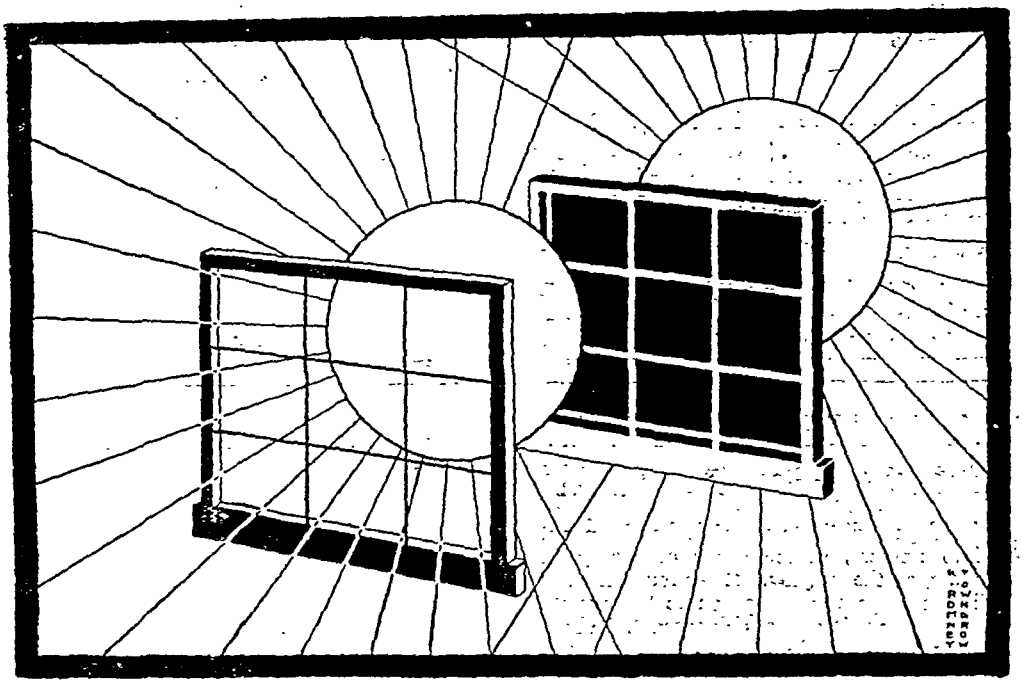
WATSON BAKER COMPANY, WEST END LANE, BARNET, HERTS, ENGLAND.



A GENTLE RESTORATIVE IN CONVALESCENCE

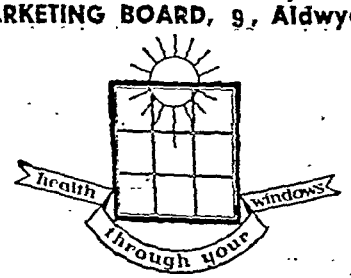
"Vita" Glass is a practical measure to prescribe for patients Installed at a moderate cost

At one time the medical practitioner had some hesitation in suggesting the "Vita" Glass window to his patients because of the considerable expense involved, but nowadays, enough "Vita" Glass for an average sized bay window in a modern house costs about 38/- plus the cost of fixing.

By allowing free passage to the active ultra-violet rays "Vita" Glass assists in the recovery of patients who cannot be taken outdoors with safety owing to the risk of cold winds and sudden changes in temperature. It provides a gentle stimulation which is of the utmost value during convalescence.

An account of the ample demonstration that "Vita" Glass has given of its power to transmit ultra-violet light will be forwarded to any interested medical man. Write to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C. 2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens

V. 154

A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

A MEDIUM FOR THE PEAT DISTILLATE PRINCIPLE

THE peat distillate principle has been put into harness, in the shape of sphagnum moss, by the surgeon. It has found its way in the shape of bog water, into the age old pharmacopœia of the Irish peasant. In both instances it has justified its use again and again.

The makers of Sphagnol preparations have devised a variety of convenient media for this principle, an ointment, soaps (Medical, Toilet, and Shaving), a lotion and suppositories. In each case the strength is from 5 to 15 per cent. and the medium of the highest quality. The preparations are on sale at all chemists at very reasonable prices.

Medical practitioners who would like to test the maker's claims will be supplied with generous free samples on application to Peat Products (Sphagnol) Ltd. (Dept. B16), 21, Bush Lane, London, E.C.4.

SULPHAQUA

LARGELY AND SUCCESSFULLY PRESCRIBED IN

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Injunction TREATMENT OF SYPHILIS with Mercury.

Employed in BATH and TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties. Relieves intense Itching and Pain, is *WITHOUT OBJECTIONABLE ODOUR*, and does not blacken the bath enamel. Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhoea of the Scalp. Largely used in dermatological practice.

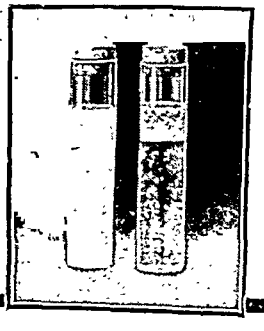
SAMPLES AND LITERATURE ON REQUEST

HANDFORTH LABORATORIES,
CLAPHAM ROAD, LONDON, S.W.9.

Action of Antiseptics on Organic Salts

Important Findings

The left hand test tube below shows Lysolat in a state of perfect emulsification in a 3% solution of Sodium Chloride, whilst a well-known liquid Lysol (right hand test tube) has broken down under the same conditions.



One of the problems of antiseptic practice has been the rapid deterioration of emulsified disinfectants on contact with organic matter. As doctors know only too well, the salts break up the emulsion, throw out the active principle of the antiseptic, and destroy its bactericidal value.

Experiments with 10% solutions of many lysols and other disinfectants in wide use have revealed that Lysolat alone preserves a perfect emulsion in salt solutions and in sea water; in fact, a solution of 3% sodium chloride, or for that matter any chloride, would destroy any other cresylic acid preparation, whether proprietary or otherwise.

Surgeons will realise the significance of these tests, for obviously the physical action of the antiseptic in disintegrating dirt, grease, and blood clots, and attacking the bacteria within, remains unimpaired. Lysolat is specially sensitised with a protective colloid, which preserves its efficacy under the most difficult conditions encountered by the surgeon or the chemist.

Lysolats

PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1.3 and 2.- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

In Acute Staphylococcic Infections

In the treatment of acne, erysipelas, furunculosis and other acute conditions arising from staphylococcic and streptococcic infections the intramuscular injection of Manganese Butyrate B.D.H. is being practised with considerable success; also in the treatment of acute complications which occur in the later stages of gonorrhœa, clinical evidence has demonstrated the remarkable value of injections of

Manganese Butyrate B.D.H.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7

ALOCOL

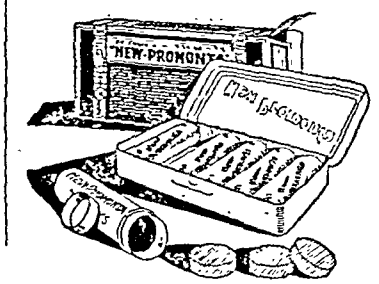
Colloidal Hydroxide of Aluminium

A SPECIFIC FOOD FOR NERVE AND BRAIN CELLS

WHEN nerve and brain cells become impaired through the slowing-down of active and healthy cell-metabolism normal conditions can quickly be restored by the administration of Lipoids possessing a definite organ specificity.

In "NEW-PROMONTA" medical men have at their disposal an organic food rich in Nerve Lipoids in Phosphatides and Cholesterols, which by a special process are preserved in the identical quantities and conditions in which they exist in the living cells. "NEW-PROMONTA" assists metabolism and restores debilitated cells.

"NEW-PROMONTA" has other valuable constituents—Lime, Hæmoglobin, Iron, Albumines, and the Vitamins A, B, D, and E—which make it a very excellent tonic food and body builder in the treatment of malnutrition, debility, and all nervous disorders.



TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA" will be sent post free to any Doctor, Clinic, or Hospital on application.

"NEW-PROMONTA" in Tablet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket which holds a day's supply. "NEW-PROMONTA" in powder form is supplied in sealed air-tight boxes of ½-lb. at 3/-, and ¼ lb. at 5/6.

THE FRENCH NATURAL MINERAL WATER

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. Vichy-Celestins, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

Solving a Food Problem

HOVIS

Most nourishing Bread

After all the discussions as to the relative values of white, wholemeal, and various brown breads, it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as HOVIS, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time, impairs health, and, with children, prevents perfect development.

HOVIS, even in small quantities, provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

HOVIS Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "brownness" of bread is not a measure of its vitamin content. HOVIS does not contain bran, and is easily digestible.

Note the following figures showing the Vitamin B content of milling products and yeast in 100 g. dried bread:

White Bread	200
Wholemeal Bread	1,450
HOVIS Bread	2,600

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals HOVIS.

Toxæmias of Pregnancy

Biochemistry and Endocrinology prove beyond dispute that pregnant women are weakened in their defences against general disease and septic invasions.

A lowered resistance, often accentuated by the modified shock of parturition, makes PUERPERAL SEPSIS only too simple a matter in many cases, in spite of faultless obstetric technique.

The toxæmias of pregnancy have been investigated and illuminated extensively in the past ten years by the patient research of many brilliant observers, who are all emphatic in representing the importance of intestinal toxæmia in the puerperal picture. Their conclusions point to the necessity of providing

A Safe Intestinal Bactericide

to promote the well-being of mother and child by limitation of putrefactive changes in the bowel during the later months of gestation, and until the post-puerperal period is passed.

Such a product is now available in the form of Dimol, the effect of which can be readily estimated by the gradual disappearance from the urine of the toxins—tyramine, indican, skatol, etc.

The Obstetrician who wishes to push his investigations into the fascinating subject of the influence of intestinal toxæmia upon intra-uterine life is now furnished with a powerful weapon of research.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

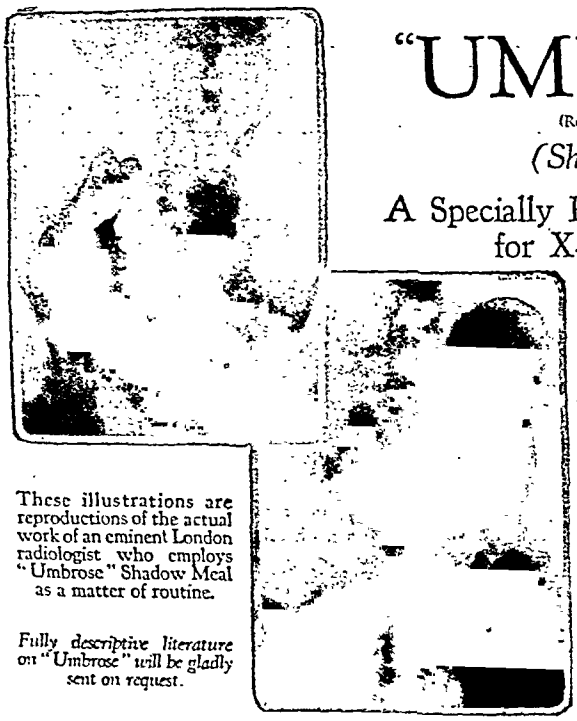
WRIGHT'S LYSOL

Emphasise "WRIGHT'S" to your patients

To tell them to ask for Lysol is not enough, for you know that there are Lysols available which are caustic and irritate the skin. Wright's Lysol is safe. It is British owned and British made — analytically controlled by the Rideal-Walker test which guarantees unvarying purity. It contains no free alkali, cannot injure delicate membranes and gives certain results. The medical profession has endorsed the use of Wright's Lysol for the past seven years. Your patients should know the safety that is in the name. *British Owned and British Made, by the makers of the famous Wright's Coal Tar Soap.*



These illustrations are reproductions of the actual work of an eminent London radiologist who employs "Umbrose" Shadow Meal as a matter of routine.

Fully descriptive literature on "Umbrose" will be gladly sent on request.

"UMBROSE"

(Registered Trade Mark)

(Shadow Meal)

A Specially Prepared Barium Meal for X-Ray Diagnosis

The high degree of opacity of "Umbrose" ensures perfect shadow definition on the X-Ray plate. Other notable advantages of this meal are its freedom from toxicity, exceptional fineness, palatability, and the fact that it may be simply and quickly prepared in the X-ray room.

"Umbrose" (Shadow Meal) is prepared in three sizes as follows:

No. 1 contains 2 oz. $BaSO_4$
No. 2 „ 4 oz. „
No. 3 „ 6 oz. „

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

Messrs. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Intestinal Disinfection

ALLERGIC CONDITIONS & PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (e.g., animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, etc.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases. The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

"SMILER"

HEAT TREATMENT of MILK

The unanimous results of recent researches on milk as a food for the Infant have shown that processes which adopt intensive temperature periods, such as are necessarily employed in pasteurisation, the preparation of evaporated milks, and spray process dried milks, have a disturbing influence on the calcium and phosphorus of the milk, and consequently on the retention by the Infant of these important elements. In addition, it has been shown by various investigators that such processes have a destructive effect on essential vitamins.

Cow & Gate Milk Food

Cow's Milk made safe and suitable for Baby.

On the other hand, such drying processes—as 'C & G' process, in which the milk is held for a matter of a few seconds at a high temperature—have been shown to be free from the above disturbances, and the full nutritive and vitamin value of the original rich West Country milk is preserved intact.

Made under strictly hygienic conditions and under expert supervision, Cow & Gate is uniform in its outstanding properties, and standard in its composition throughout the year.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

The Standard of Purity of

INSULIN "A.B." Brand

TRADE A B MARK

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have never involved the slightest sacrifice of quality.

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

LIVER THERAPY
IN
ANÆMIA

The efficacy of treatment with Liver or Liver Extract in cases of Pernicious Anæmia is now recognized. The blood picture rapidly returns to normal and apparently remains so indefinitely while the treatment is continued. It still remains to be seen whether permanent cure is possible, but it is known that usually, when the erythrocyte count has been raised to a satisfactory level, a reduced dosage will protect the patient against relapse. Liver therapy is also effective in certain cases of Secondary Anæmia, especially when due to failure of blood regeneration after hæmorrhage. This effect is greatly enhanced by simultaneous administration of iron.

HEPATEX

This is the liquid extract of liver made at Evans' Biological Institute, the method of preparation ensuring that the whole of the therapeutic principles are contained in the final product. Being concentrated so that 1 oz. equals 1 lb. of fresh liver, it is the most convenient form of liver extract for oral administration. It has been tried clinically with notable success.

Supplied in 4 oz. bottles at 12s. per bottle.

Each bottle contains sufficient for 8 days' full treatment

Prepared at Evans' Biological Institute, Runcorn.

THE EMPEROR 漢武帝 (WU TI), THE CHIEF PIONEER IN THE ESTABLISHMENT OF RELATIONS BETWEEN CHINA AND THE WEST, UNDER WHOM THE PRESTIGE OF THE EMPIRE REACHED GREAT HEIGHTS.—Wu Ti pressed into the service of the state all the talent the land afforded, by calling upon all men of genius to present themselves at court to assist in the government of the empire. He thus secured, among many others, the services of Li Kuang and Chang Ch'ien who carried out military and exploring expeditions in Central Asia. Chang Ch'ien was the first to penetrate to the extreme west. He endured captivity in Bactria for ten years, from which he escaped by way of Fergana, bringing back with him to China the walnut and the cultivated grape. He taught the art of wine-making, which he had learned from the Persians, and is said also to have introduced hemp. Wu Ti, later, sent him to negotiate with the West, and, in 115 B.C., he returned, having made treaties and established intercourse with 36 States. All these efforts were the outcome of the emperor's great desire to establish a safe route for the silk trade between China and the West. Sze-ma Ts'ien, another man of genius, was employed to reform the calendar, and from this time onwards China had an accurate chronology. Wu Ti had canals dug and ports constructed; he was an enthusiastic patron of literature and music, instituting classical degrees and establishing academies. Magnificent buildings were erected during his reign and the court lived in great splendour.

Observations
ON
THE RELATION OF MALIGNANT DISEASE TO BENIGN TUMOURS OF THE INTESTINAL TRACT.*

BY
M. J. STEWART, M.B.Glas., F.R.C.P.Lond.,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF LEEDS.

THE subject of our discussion is not new, but it is one to which considerable attention has been devoted in recent years, and it may be useful if, at this time, we endeavour to bring together such facts as we may think we have ascertained in the course of our labours, and such speculations as may help to give a clue to our obscurities. In particular it is desirable to know to what extent we are in agreement on the main issues, and wherein individual experience differs.

In going over the data, anatomical and documentary, which I have accumulated on this subject during the last twenty years, I have been surprised at both its amount and its variety. Simple tumours of the alimentary tract, like so many other unobtrusive lesions, are found with considerable frequency when carefully looked for, and, while usually of little clinical importance *per se*, in a certain proportion of cases they are attended by the most serious consequences. It is with one of these consequences, the development of malignancy, that we are *concerned to-day*.

As opener of the discussion it will probably be most convenient if I pass in review the various kinds of simple tumours which occur in the alimentary tract, considering at the same time the incidence and nature of the malignant changes to which each is liable. Subsequent speakers can then extend and elaborate those aspects of the problem in which they are particularly interested. My own remarks will be based chiefly on my personal experience of human *material, but it is hoped that during the discussion* the comparative and experimental sides will not be neglected.

CONNECTIVE TISSUE TUMOURS.

Simple connective tissue tumours of the alimentary tract are of comparatively infrequent occurrence, the only two of any consequence being lipoma and leiomyoma. I have encountered only five examples of submucous lipoma of the stomach, all of them small and sessile, mere casual findings at necropsy. In another case there was a pedunculated lipoma the size of a hazel-nut at the junction of the first and second portions of the duodenum. It also was a casual finding; but tumours of this type elsewhere in the intestines may be the starting-point of intussusception. Subserous lipomas are more common. They really arise in the mesenteric adipose tissue, are not infrequently multiple, and seldom attain a large size. Lipomas in general rarely undergo malignant change, and I am not aware that any case of the kind has been reported in connexion with the intestinal tract. Leiomyomas are much more common and occur chiefly in the stomach and oesophagus. They are most frequently met with casually in the post-mortem room as small, flat, sessile, button-like growths, measuring up to one inch in diameter and projecting slightly from the mucosal surface. This is due to the fact that they usually originate in the inner layer of the muscular coat and naturally project in the line of least resistance. These tumours grow slowly, and very rarely attain a large size. Of twenty-two cases of leiomyoma of the stomach which I have encountered, the largest was no bigger than a walnut. It was rounded, lobulated, and semi-pedunculated. In the museum there is shown a leiomyoma of the ileum fully two inches in diameter which had caused obstruction and which was successfully removed at operation. The cut surface shows the characteristic whorling of these growths. As with uterine fibroids, alimentary tract leiomyomas occasionally become sarcomatous. In the uterus it may be possible to trace the sarcomatous change in one out of several fibroids present, but in the gut, where single tumours are the rule, considerable doubt may remain as to whether a spindle-cell leiomyosarcoma has originated in a simple myoma or has been malignant from the outset. In this connexion it may be mentioned that myosarcoma appears to be more frequent in the small intestine than in the stomach, whereas the reverse is the case with regard to myoma. Unstriped muscle tissue also enters into the composition of the so-called adenomyomas of the stomach and intestine, tumours which will be discussed later.

EPITHELIAL TUMOURS.

The simple epithelial tumours are undoubtedly the most important members of the group now under discussion, not only because they are dangerous in themselves as a cause of haemorrhage or obstruction or as the starting-point of intussusception, but also because they are with good reason suspect as precancerous lesions. In structure they are generally adenomatous, but a villous papilloma is also encountered, particularly in the rectum. Starting as small flat patches of glandular overgrowth, these tumours tend to become polypoidal at an early stage of their career, and in this form they may ultimately attain a considerable size, as much as one or two inches in diameter. They show a notable tendency to multiplicity, especially in the large intestine, and occasionally there may be several hundred present. The conversion of the tumour from a wholly sessile plaque to a pedunculated polypus is brought about chiefly by the muscular movements of the gut, aided, perhaps, by the action of gravity. The pedicle is often quite definitely composed, not of tumour tissue, but of pulled-out normal or much thinned mucosa—an important point in relation to the surgical treatment of solitary polyps. The muscularis mucosae is dragged inwards with the rest of the mucous membrane, and may show considerable increase in thickness. Its presence, unbreached by epithelium, is the best evidence that a polyp has not yet become malignant, although, as will be shown later, suspicious changes may already be visible in the mucosa. The fibrous tissue core of gastric polypi, on which Menetrier (1888) has laid stress as indicating a pre-existing gastritis, is probably rather a reactive thickening of the submucosa in response to the mechanical drag of the polyp. The relation of chronic gastritis to multiple polyps of the stomach—whence the term "gastritis polyposa"—has been emphasized by many writers, but it is difficult to account for solitary polypi in this way; yet the two lesions are indistinguishable microscopically, while chronic gastritis, without any suggestion of polyposis, is a common accompaniment of both ulcer and cancer of the stomach. In the colon the corresponding lesion, colitis polyposa, is sometimes familial. In its early stages Ewing (1928) finds that there is a diffuse and pronounced hypertrophy of the entire epithelial lining, which supports Versé's view that the sole element in the predisposition is the excessive reaction of the epithelium to irritants. Here again it is difficult to account for solitary polypi on an inflammatory hypothesis.

Relation of Adenoma to Carcinoma.

The connexion between simple adenomata of the intestine and carcinoma is now well established. Dukes (1925–26), who has investigated this question with great thoroughness, found that of 33 consecutive cases of carcinoma of the rectum and sigmoid operated on at St. Mark's Hospital no fewer than 25 showed the presence of adenomata. He considers that this figure—75 per cent.—is probably an underestimate, since only the surgical specimens were available for examination, and adenomata may have been present elsewhere in the intestine. I show in the museum several interesting examples of this association, including a case in which widespread polyposis was associated with two independent carcinomata, one in the rectum just above the anus, the other some ten inches higher up. As both Dr. Dukes and Dr. Susman are taking part in the discussion, I will leave them to deal in greater detail with this very important part of the subject.

So far as the stomach is concerned, opinion is hardening in the same direction. Cruveilhier (1835–42), who figures

* Made in opening a discussion in the Section of Pathology and Bacteriology at the Annual Meeting of the British Medical Association, Manchester, 1929.

a beautiful example of multiple gastric polypi in his great atlas, expresses the opinion that malignant degeneration of polypi ought to be frequent, and thinks it possible that many of the cancerous vegetations of the pylorus or its neighbourhood which are met with not infrequently may have originated in this way. The cancerous evolution of gastric polyadenoma has been especially emphasized by Menetrier (1888; Menetrier and Clunet, 1907), and in recent years a number of writers have expressed a similar opinion. Thus Brunn and Pearl (1926) collected 84 cases of diffuse polyposis of the stomach, of which 10 (12 per cent.) were malignant, while in Mills's (1922-23) series carcinoma at or near the pylorus was present in 4 out of 20 cases (20 per cent.).

My own experience of gastric polypi, now a considerable one, affords further evidence of the sinister significance of these ostensibly harmless growths. In the course of 11,000 necropsies performed at the Leeds General Infirmary during the last nineteen years (1910–28) there were 47 cases (0.43 per cent.) in which gastric polypi were present—namely, 27 with single polypi, 7 with two, 1 with three, and 2 with four, while in 10 cases there were numerous polypi. The same series of necropsies included 263 cases of carcinoma of the stomach. The association of the two lesions is shown in the following table.

Polypi and Cancer of Stomach.

	No. of cases with polypi.	No. associated with carcinoma.	Percentage of cases of polypi with carcinoma.
Single	27	6	22
Multiple	20	7	35
	—	—	—
	47	13	28

Looked at from the opposite standpoint, 13 out of 263 cases of carcinoma of the stomach (4.9 per cent.) were associated with polypi. This is approximately one-third the frequency (15.7 per cent.) with which, in my clinical series, carcinoma originated in relation to simple chronic ulcer. The contrast with Dukes's figure for carcinoma and polypi of the rectum and colon (75 per cent.) is remarkable.

In two other cases a single simple polypus of the stomach was associated with carcinoma of the colon. In three cases only was it possible to say with certainty that the carcinomatous change had originated in a polyp. In the others such an origin could not be excluded, although in certain of them the polypi were some little distance from the malignant growth. Six of our cases are shown in the museum. Two of these, which have already been published in abstract in the *Proceedings* of the Pathological Society of Great Britain and Ireland (Stewart, 1913–14, Gleave, 1923), are beautiful examples of multiple polyposis with carcinoma. A third case, which has been reproduced in the Atlas of Pathological Anatomy of the *British Journal of Surgery* (Fasciculus II, pp. 130–133), is of particular interest in that a large gastric polypus was found at operation together with a number of small sessile polypi. Partial gastrectomy was performed, from which the patient made a good recovery; but five weeks later she died rather suddenly and quite unexpectedly. At necropsy an unsuspected carcinoma at the cardia was disclosed, together with extensive secondary deposits in the liver and regional lymph glands.

Simple adenomatous polypi of the stomach, whether single or multiple, must therefore be accepted as a definitely precancerous lesion, but the available evidence goes to show that the association is much less intimate than in the case of the large intestine. In both sites one can occasionally trace the sequence of events with the microscope; more often this cannot be done. Usually malignancy develops at one point only, as in experimental tar cancer of the skin, but exceptions to this rule are not infrequent. Lockhart-Mummery and Dukes (1928) believe that with the progressive enlargement and dissemination of the malignant tumour there is accompanying retrogression of the hyperplastic changes and benign tumours surrounding the growth. Sometimes the pedicle of the polyp becomes so attenuated that the latter breaks off and is discharged per rectum (Ewing, loc. cit.).

Criteria of Early Malignancy in Gastro-intestinal Polypi.

It is not always possible to say definitely that a given polypoidal tumour of the stomach or intestine is malignant. The most important criterion is epithelial invasion of the muscularis mucosae, especially if this is associated with atypical cellular characters—cellular and nuclear heteromorphism, nuclear hyperchromatism, and the formation of solid epithelial masses or irregular acini. There is very little risk of confounding the obviously simple heterotopic tumours, deep in the wall of the gut, with malignant penetration. The chief difficulty arises in connexion with tumours where the muscularis mucosae has not been penetrated, but in which irregular cellular characters and de-differentiation of epithelium are present. These changes are frequent in both gastric and intestinal polypi, and while one cannot say that they certainly indicate the commencement of malignancy, they must be viewed with grave suspicion. In cases of this kind the examination of further sections from the same or another block will sometimes reveal early penetration of the muscularis mucosae.

ADENOMYOMA AND PANCREATIC HETEROTOPIA.

These closely related lesions occur in the stomach, duodenum, and small intestine, the former as something of a rarity, the latter with comparative frequency. In a consecutive series of 5,700 post-mortem examinations at Leeds there were 7 examples of adenomyoma and 22 of pancreatic heterotopia, distributed as follows:

	Adenomyoma.	Heterotopic pancreas.
Stomach	4	4
Duodenum	0	15
Small intestine	2	1
Meckel's diverticulum	1	2

A. L. Taylor and I have already described these formations in detail (Stewart and Taylor, 1925; Taylor, 1927), and it need only be said here that there is no evidence that either of them is specially liable to malignant transformation. Only three examples of pancreatic carcinoma arising in the stomach or intestine have been described (Herxheimer, 1913; Seidelin, 1912–13; and Nicholson, 1923), yet, as the above figures show, pancreatic heterotopia in these situations is of fairly frequent occurrence. I have no knowledge of a carcinoma arising in a pre-existing adenomyoma.

CARCINOID TUMOURS.

The carcinoid tumour of the appendix and small intestine, like rodent ulcer of the skin, occupies an intermediate position between the simple and the malignant tumours. It is locally infiltrative, very slowly growing, and, in the appendix, eminently amenable to surgical treatment. In rare instances dissemination to the regional lymph glands or even to the liver may occur. Taylor and I (1926), in a careful search of the literature, found only 18 published cases. This event, when it occurs, must be regarded as part of the natural history of the disease; there is no evidence that these tumours undergo a malignant metamorphosis of the kind we are considering to-day.

EXPERIMENTAL PATHOLOGY.

From the experimental side there is little to report directly bearing on this subject. Fibiger's (1913, 1914) classical experiments in the production of gastric carcinoma by feeding with *Gongylonema neoplasticum* may be mentioned, since the definite sequence of chronic inflammation, papillomatosis, and cancer was produced. These changes, however, are not strictly comparable with those occurring in man, inasmuch as they are confined in their origin to that portion of the stomach which is lined by squamous epithelium. Curiously enough, one of Fibiger's rats had a large pedunculated adenopapilloma of the colon, but as this was entirely free from parasites it was presumably an independent formation.

Bullock and Rohdenburg (1918) carried out a series of experiments in rats by introducing into the stomach mechanical and chemical irritants, the former consisting of celluloid balls covered with bristles and cork balls armed with pin-points, the latter of scharlach R and pine-tar,

either applied directly to the gastric epithelium or injected into the wall of the organ after gastrotomy. Extensive epithelial proliferative changes and even a certain amount of infiltration followed, but in no case did they succeed in producing a lesion which they were prepared to accept as carcinomatous. In the glandular region of the stomach the lesions resembled cystadenomata.

Ishibashi and Otani (1921) introduced 0.5 c.cm. of coal-tar into the submucosa of the stomach and intestine in rabbits, and two weeks later found in the stomach papillary adenomas, which, after fifty days, had shown no evidences of regression. In the intestine there was only a slight hyperplasia, with no sign of adenomatous proliferation.

Leitch (1923) injected tar per rectum in rabbits three times a week for over eight months without producing any evident tumour formation in the rectal mucosa, although in several cases papillomata formed on the skin outside the anus. Experiments in rats were equally unsuccessful.

Menetrier (1924; Menetrier and Derville, 1924), on the other hand, succeeded in producing an infiltrating squamous carcinoma of the cardiac end of the stomach of a rat by a series of tar injections into the left perirenal region followed by a series of oil of cade injections at the same site, the whole extending over a period of eleven months. Death followed the introduction of 3 or 4 drops of pure creosote. At necropsy a squamous carcinoma of the stomach was found in immediate relation to the injected tar, all of which, however, lay outside the gastric wall. The usual sequence of changes appeared to have taken place—inflammatory reaction, hyperplasia, papillomatosis, cancer.

Schabad (1926) administered tar by the mouth and per rectum to white mice, with negative results. In the stomach there resulted only thickening and keratosis of the mucosa; in the rectum, necrosis, inflammatory changes, and cicatrization. The changes in the perianal skin, however, were those of an epithelial new growth of cancroid type.

CONCLUSIONS.

1. An important and intimate relationship exists, both in the stomach and in the rectum and colon, between simple adenomatous polypi and carcinoma.

2. The evidence goes to show that an actual malignant metamorphosis takes place in the epithelium of one or more of the polyps, although the ultimate full development of malignancy is in most cases confined to a single focus.

3. As a local factor in the etiology of cancer, intestinal polypi occupy a most important position, much more so than their gastric congeners.

4. In cases in which a single polypus only is present simple removal of the tumour with its pedicle and base may be followed by cure, even after definite carcinomatous change has occurred. In cases of generalized polyposis only extensive operative procedures with a high mortality—gastrectomy, total or partial, or colectomy—are likely to be successful in preventing the onset or checking the spread of malignancy.

5. There is a certain amount of evidence to show that sarcomatous metamorphosis may occasionally occur in simple leiomyomatous tumours of the alimentary tract, just as in uterine fibroids.

6. There is no evidence that the simple heterotopic tumours of the stomach and intestines—adenomyoma, pancreatic heterotopia, Brunnerian adenoma—are specially liable to malignant change.

7. The so-called carcinoid tumours of the appendix and small intestine very rarely undergo metastasis to lymph glands or liver. This, when it occurs, is part of the natural history of these tumours (cf. rodent ulcer of the skin), and does not indicate anything in the nature of a new or superimposed malignancy.

DIVERTICULITIS.*

BY

EDMUND I. SPRIGGS, M.D., F.R.C.P.,

SENIOR PHYSICIAN, RUTHIN CASTLE.

DIVERTICULITIS of the sigmoid colon has long been known to pathologists by various names, but until recent times was looked upon as a rare disease. We know now that it is not rare, but it still receives less space in the text-books than is given to disorders that are seldom met with and do much less harm.

It is just thirty years since a paper by Graser appeared, in 1898. This author, as far as I know, was the first to suggest that the frequency of inflammation of the peritoneum about the sigmoid colon is due to diverticula. He also made microscopic studies showing the frequency of diverticula in adults. In America, Fischer (1900), Beer (1904), Gordinier and Sampson (1906), and others published valuable studies. Special mention must be made of the paper of Mayo, Wilson, and Giffin which appeared in 1907. In this country Moynihan (1907) and Telling (1908) led the way. Dr. Telling's later paper, with Gruner, is a compendium of pre-*x*-ray studies, full of observation, reading, and reasoning. In France, the papers of Patel (1911) and of Bensaude, Cain, and Hillemand (1913) should be mentioned.

When *x* rays began to be applied to the study of diseases of the bowel a flood of new light was shed upon this as upon many other disorders. For more can be learned about the function and lumen of the bowel in a case of diverticulitis by a combined clinical and good *x*-ray examination than by a laparotomy or a post-mortem inspection. It soon appeared that whilst sigmoid diverticulitis was not infrequent, a precedent condition of the bowel in which diverticula were present along the colon, but not inflamed, was often found and was not associated with any clinical state that could be called diverticulitis. We had observed a series of these cases before 1920, and it was proposed to give them the name of diverticulosis. Soon afterwards my colleague O. A. Marxer, upon whose studies what I have to say from a radiological point of view is founded, detected a still earlier stage of the disorder, the pre-diverticular state.

There are, therefore, three main stages in the progress of the disease:

1. The pre-diverticular state } (diverticulosis).
2. The stage of formed diverticula } (diverticulosis).
3. The stage of inflamed diverticula, or diverticulitis.

We have many times observed each of these stages pass into the next. They may all be present at once at different parts of the bowel, or even in the same segment.

Although it is only the last stage which has surgical implications and is to be discussed to-day, yet something should be said about the earlier ones; indeed, they fall logically under the headings of the etiology and of the possible prevention of diverticulitis.

The pre-diverticular state was first described fully at the Clinical Society of this city in 1925. It had been briefly referred to in print by O. A. Marxer two years earlier, and was first recognized in 1920. The part of the bowel affected loses its normal segmentation and

* Read in opening a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Manchester, 1929.

presents a more rigid outline with small convexities upon it. In two cases operated upon the surgeons reported the appearance of inflammation over a part of the bowel in this state. We have had the opportunity of examining such a piece of bowel after removal. The characteristic small corrugations can still be seen with x rays in the hardened specimen at the affected area, and not at other areas. I shall refer to the histology of this specimen.

We have observed the pre-diverticular state over ninety times, and in nearly all it was in association with forming diverticula. In over twenty cases we have been able to take pictures at long intervals and prove that pouches have appeared at the part of the gut which was formerly in this state. (Figs. 1 and 2.)

In many cases no symptoms are complained of at this stage, especially if only small areas of bowel are affected, as is usually the case, the inflammation appearing to creep slowly about the bowel wall. But when large areas are affected, as sometimes happens, then pain or burning discomfort is felt.

My colleague S. W. Patterson is working at the histology of the pre-diverticular state. It is hard to get suitable material, but I may say here that we have microscopic evidence, in addition to the radiological, that there is a pathological change in the bowel wall antecedent to the formation of pouches. In this we are supported by Sir Arthur Keith, as mentioned in the last annual report of the Royal College of Surgeons. A rarefying of the bowel muscle in diverticulous areas was described by Graser and by Schreiber, also by L. B. Wilson in 1911.

As mentioned above, any part of the circumference of the bowel may be affected. The pouches, however, tend to form where the blood and lymphatic vessels pierce the wall—that is, at the weakest part—and to appear on the peritoneal surface near to, but not at, the taenia. Sometimes the pre-diverticular state is followed by irritation of the bowel, giving on the film a coarser corrugated or concertina-like outline. This corresponds to the appearance described by Keith in 1910. It may persist for a long time—a year or more. We have sometimes called this condition the aftermath of the pre-diverticular state. Later there is seen flabby diverticulous bowel, without proper haustration. Keith's suggestion was that an irregular sustained muscular contraction preceded the formation of pouches, a conclusion to which our observations led us independently. He draws an analogy between it and auricular fibrillation of the heart muscle.

The second stage of formed diverticula is often discovered at radiological examinations; in 1,000 consecutive x-ray examinations at Ruthin Castle it was found in 10 per cent., in the Mayo Clinic x-ray department in 5 per cent., and in the post-mortem room in 7 per cent.[1] In all we have now observed 313 cases of diverticulosis in 3,100 consecutive x-ray examinations of the alimentary tract. To the naked eye the little pouches look, in the post-mortem room, like pea-shaped projections from the bowel; they may be contained in the appendices epiploicae or are covered with fat and not visible. In spite of this it must remain a surprise to those of us whose lot it has been to make numbers of post-mortem examinations that their frequently was not more fully recognized in pre-x-ray days. One reason doubtless is that, like the appendix, they shrink greatly after death. The pouches may be few or many, small or large. If, as is often the case, different sized pockets can be seen they are usually in groups, those of the same size being together. Their number can be estimated best by taking a photograph after the barium meal has left the lumen. The omission of this last film in routine examination has led to underestimation of the frequency of the disease.

FIG. 1.—Oblique view of a sigmoid flexure in the prediverticular state; some small diverticula can be seen on the upper border. Note the likeness of the affected part of the colon to the piece of small intestine shown in the upper part of the picture. (See Fig. 2.)

Large diverticula with wide necks look the worst, but are not. They are often associated with loose motions, and we ascribe their size to the frequent distension from easy filling and emptying. The contents may be discharged as pellets, which can be seen in the motions, or as fragments. When the latter contain barium the powdery track can sometimes be detected on the film taken after the lumen of the gut is otherwise empty.

Smaller pouches with narrow necks are less obvious but more harmful. The barium may not be able to fill them owing to the retention of food residues. We then see characteristic wineglass or crescentic shadows, the barium *occupying* the neck of the pouch and creeping partly round the retained matter. In such pockets the contents are liable to become dried up and form the stercoliths, which are believed to be a frequent starting-place of diverticulitis.

FIG. 2.—The same piece of intestine as in Fig. 1, after an interval of three and a half years, showing developed diverticulosis. Numerous diverticula are seen.

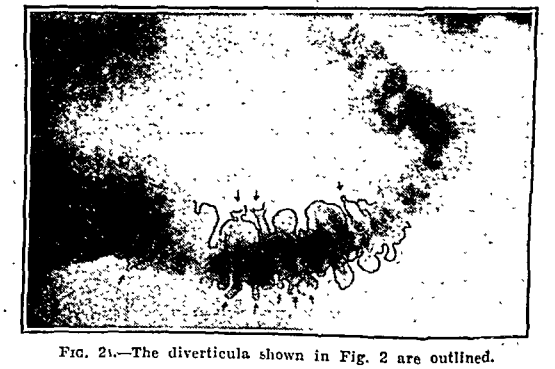

FIG. 2a.—The diverticula shown in Fig. 2 are outlined.

The microscopic features of the pouches are that in some the mucosa and submucosa are seen to penetrate the muscular coats of the bowel. In many, however, the muscle layers are also represented in the wall of the pouch.

The etiology of diverticulosis is not yet understood. The incidence in middle age points to the pouches being acquired and not congenital. We have also seen them repeatedly with x rays in a bowel which had shown none years before—that is, we have observed their development. They were formerly thought, and are still assumed by some, to be simple pulsion pouches formed as a result of internal

pressure at weak parts of the bowel wall. This cannot be gainsaid, but there is some other factor as well; for the diverticula often occur in groups, which, in a series of observations, can be seen to form at different parts of the bowel at successive times, and to be preceded by the pre-diverticular state above described. The appearance is that of an inflammation. It is, whether casually or causally, associated with infective foci in other parts of the body, especially of the teeth, and with some degree of spondylitis, usually lumbar.

Constipation has been regarded as a cause, and this is copied from paper to paper. But, as *Telling pointed out*, the disease is twice as common in men as in women, whereas men are less liable to constipation; and there was rather less *constipation*, as determined radiologically, in a hundred of our cases than in a hundred other patients of the same age and sex. We think it quite as likely that aperients are one cause, and that abnormally liquid faeces lying in the sigmoid flexure may, by bacterial or chemical damage, have to do with the frequency of the disease in that part of the gut. The benefit which follows an anti-constipation regime without irritant aperients will support either view. The not infrequent observation that a renewal of symptoms is associated with the accession of new disease, with fresh tiny diverticula, close to an indurated area of bowel, suggests an active bacterial process rather than mere weakness from the chemical damage of stasis.

Although diverticulosis may be quiescent, in about half the subjects symptoms are complained of, especially constipation, flatulence, and abdominal pains or discomforts. Less common symptoms are diarrhoea, or irregularity of the bowels, painful or frequent micturition, headache, malaise, and nausea. There is often a disposition to the lumbago associated with spondylitis.

Definition of Diverticulitis.

Strictly speaking, whenever any little pouch is the seat of inflammation, the patient is the subject of diverticulitis. But for clinical purposes we reserve the term for the stage at which inflammation arising from a diverticulum has spread to a considerable area of the wall of the bowel, involving most, if not all, of its thickness. This process often begins at the neck of a diverticulum with a narrow outlet, containing a stercolith. Some pouches show these characteristics at a very early stage, for we often see minute herniae with the appearance of lith-bearing diverticula. The inflammation, once started, thickens and contracts the haustrum, as shown in a former paper.[2] As this process extends the clinical, radiological, and pathological features become characteristic. The short description that follows is founded on a study of 71 cases of diverticulitis under my own care.

Clinical Features.

The clinical features of diverticulitis are those of a low form of inflammation in the large bowel, usually in the left lower quadrant of the abdomen, spreading to neighbouring structures. Abdominal discomfort, less often pain, not as a rule related to food, is situated about or below the navel, but especially in the left iliac fossa. It may be intermittent, with intervals of several weeks or longer. The pain can be severe, and is often accompanied by a feeling of ill health; it may take the form of a dragging sensation and backache. Flatulence and a feeling of distension are usually mentioned, and may be the only symptoms; an advanced state of diverticulitis may, indeed, be present with but little complaint; in several there was no pain. Constipation, irregularity of the bowels, diarrhoea, or a sense of incomplete evacuation is frequent. The increasing constriction leads slowly, usually very slowly, to obstruction.

In cases of implication of the bladder there may be frequent micturition, sometimes painful, after the bowels are opened; or a painless micturition may be followed by pain in the tumour. This symptom may be due to adhesion of the inflamed gut to the bladder, but it is complained of in cases in which radiological evidence of adhesion cannot be made out.

A sausage-shaped tumour, sometimes tender, but not always, can be felt in the left iliac fossa or below the brim of the pelvis, except in the very obese. It may become acutely inflamed, with pyrexia and vomiting. The tumour often varies, in earlier stages, in size and hardness. Diverticulitis sometimes occurs at other parts of the colon; a result of abscess will vary ent and site of the secondary per rectum, excluding that is not usual, the inflammatory lesion lying as a rule without the mucous membrane; the disease is, indeed, as it was formerly named, a peri-diverticulitis.

There appears to be a liability to lumbago, sciatica, and shingles.

Radiological Features.

The radiological features of diverticulitis are definite. With a barium meal or enema, typical rounded, oval, or crescentic shadows of the barium in the diverticula will usually, though not always, be recognized in the neighbourhood. They are not, however, the characteristic features: these are (1) the rounded or serrated inopaque intrusions into the barium-filled lumen due to swollen mucosal folds; or (2) spike or palisade-like projections of barium shadows from the lumen of the bowel, the wall of which is thickened from inflammatory exudation, and fixed. They represent deformed and contracted haustra. In this second form serial films, when superimposed, show no variation in the outline of the shadows, although there may be vigorous and irritable contractions of the bowel wall above and below, or even in the same segment of the gut opposite to the rigid area.

On closer observation, and with increasing experience, we find that when there is exacerbation of symptoms there is often a new attack of diverticulosis—that is, either the pre-diverticular state or minute pockets, or both, can be seen close to the old areas of disease, and may be accompanied by fresh swelling of the mucous membrane.

Pathological Features.

The pathological features are those of a chronic inflammation of the pelvic colon, arising at first from one or more diverticula, but now involving the coats of the gut, including, sooner or later, the peritoneal coat, and spreading to surrounding parts; especially to the bladder in men, but also, at times, to the small intestine, or abdominal wall; and, in women, to the uterus and ovary. Leucocytosis is frequent. In late stages small, or sometimes larger, abscesses form in the inflamed or septic area. Metastatic abscesses are unusual, but have been recorded. Ulceration of the mucous membrane is rare, whereas in cancer it is the rule. In time the chronic inflammation leads to fibrous thickening of the wall of the gut, cutting off the diverticula from their necks. In some cases at length the appearance is that of a scirrhous narrowing of the bowel with a wall half an inch to an inch thick.

Symptoms.

From a consideration of our cases it appears that symptoms are more likely to occur at the first and last stages of the disease. For example: a man of 64 had pain and discomfort in the left iliac fossa twenty-six years ago. His doctor remarked that it was like a left-sided appendicitis, but with rest and enemas the symptoms subsided and he was well for many years. Some four years ago intermittent discomfort and pain began in that region. On admission the thickened bowel could be felt in the left iliac fossa. It is likely that the first symptoms were those of the acute stage of an extensive pre-diverticular state such as we have observed in other patients, that the middle period of quiescence was that of the developed diverticula, whilst the third stage, with recurring symptoms, is shown to be due to new disease with fresh pockets arising on the old areas and with the inflamed mucosal folds of diverticulitis.

Diagnosis.

The diagnosis of diverticulitis is not difficult if the comparative frequency of the disease is kept in mind. The long history and well-being of the patient in the intervals of symptoms are characteristic. The absence of bleeding or mucus is against malignant disease, though their

presence does not prove it, for they may both occur in diverticulitis. Of late it has become common for the diagnosis to be suggested or made before admission, or before *x*-ray examination. It is, however, not infrequently found when it has not been suspected, as must always be the case when no symptoms have arisen.

In all chronic cases, except those which have gone on to abscess with severe constitutional symptoms, a competent *x*-ray examination, if obtainable, is essential, and establishes the diagnosis. The chief common errors are to diagnose diverticulitis because some diverticula are seen, and to miss diverticulitis because the piece of bowel affected is not brought into profile, often no easy matter among the coils of the sigmoid flexure. When a narrowing is present without the characteristic appearance of diverticulitis, the presence of diverticula near by, as shown by a barium meal or enema, makes it probable that the case is one of diverticulitis; but the possibility of cancer being also present is not excluded.

The sigmoidoscope usually gives negative information; it may show the under aspect of a stricture without the nodules which accompany a cancerous ring.

Other diseases to be thought of are tuberculous, syphilitic, and actinomycotic inflammations of the sigmoid, diseases arising from neighbouring parts, and left-sided appendicitis.

OBSTRUCTION.

An attack of diverticulitis with threatened obstruction may occur as a result of two conditions which differ widely in their ultimate gravity.

1. *Inflamed Mucosal Folds.*

This condition may be due to local inflammatory swelling of mucosal folds with little or no implication of the other layers of the bowel wall. The folds are, of course, transparent to the rays and give the appearance of rounded or serrated intrusions between the barium-filled haustra; they do not advance and recede, like the normal lining, with segmentation; but it will be seen on superimposing the tracings in a series of photographs that the bowel wall is mobile. This may be the only way in which these swollen folds can be distinguished from the more permanent inflammation which involves all the coats.

The first sign in these cases may occur from threatened obstruction due to inflammatory swelling of the folds. This was so in several of the cases here reviewed. A typical history is as follows. A man who has had for some time discomfort in the lower abdomen, associated often with defaecation, is seized with pain round the navel, distension, and nausea, the temperature rising to 101° or thereabouts. There may also be pain on micturition.

On examination a tender area is found in the distended abdomen, usually in the left iliac fossa, and sometimes the thickened bowel can be felt. There is desire to pass a stool, but the attempt fails. The clinical state is one of intestinal obstruction, but is not of the same severity as those forms of stoppage, such as strangulated hernia, in which the circulation through a part of the bowel is blocked.[3]

The importance of diagnosing this condition is that with careful douching or warm oil enemas the swelling will go down rapidly and relief is obtained. For example, a patient was threatened with obstruction nine years ago, but the symptoms yielded to enemas. Examination later showed diverticulosis and swollen mucosal folds in the descending colon, but not rigidity of the bowel wall. With a careful regime and periodic treatment there has been no recurrence.

It may be assumed that many cases of obstruction relieved by enemas, and some of those in which, after a colostomy, the parts have been restored with success, are in this group.

2. *Fibrous Constriction of Bowel Wall.*

A threatening of obstruction may be due to fibrous contraction of the whole bowel wall. In some cases the mucous membrane escapes inflammation. In most there is also swelling of the mucosa, but not in big folds, and the wall is rigid. The risk of obstruction is here much greater, though in this form also douching may give relief, which, with treatment, may continue over a long period.

When in this group the channel is becoming permanently too narrow chronic dilatation of the gut above the constriction may be observed.

PROGNOSIS.

The prognosis in diverticulitis depends upon how soon the disease is recognized and treated. So far as ten or twelve years' experience can teach, it appears probable that in all early and in most advanced cases the disease can be arrested and kept indefinitely in check by suitable treatment. In advanced disease with a too narrow lumen of the bowel, if the area is localized and surrounding organs are not implicated, resection may be practicable, with a prospect of complete relief. In others, if colostomy be done, the outlook for life is good, and in a few of these a further operation after much of the inflammation has subsided may restore the parts. If abscesses have formed and there are severe constitutional symptoms the outlook is grave.

TREATMENT.

The treatment of an early case of diverticulitis is the same as that of diverticulosis, and consists in keeping the body, the alimentary canal, and especially the mouth and the colon, as healthy and clean as possible. Any source of sepsis that can be reached must be removed. The diet should be simple and regular, with a good deal of fruit and vegetables, and little meat. A diet which is found useful is the following, but the preference and state of each person must be considered.

8 a.m.—Coffee and milk; one tablespoonful of milk sugar; wholemeal bread; butter; honey or marmalade.
1 p.m.—Fish (cooked any way); butter sauce; salad and dressing; compôte of fruit; cream; toast and butter.
4 p.m.—Coffee or weak tea, with milk or cream; marmalade; wholemeal bread (toasted if desired) and butter.
7.30 p.m.—Vegetable soup; some egg dish (poached, scrambled, or omelette) with vegetables or fruit—for instance, jam or jelly omelette or omelette aux fines herbes; cream cheese; wholemeal bread; butter.
10 p.m.—Half an ounce of paraffin in 2 ounces of warm milk.

Meat is given two or three times a week to begin with, but later added daily, if desired, provided that regular actions are established. The milk sugar is a pabulum for the *Bacillus acidophilus*, which is given as mentioned below.

If there is such a degree of inflammation of the mucous membrane as to make it undesirable to give fruit, greens, or wholemeal bread, an entirely non-irritating or bland diet of cereals, milk, with fish or meat, is needed, at all events for a time. For example:

Breakfast.—Bread-and-butter; jelly marmalade; coffee and milk.
Lunch.—A light meat dish or fish; potato; milk or steamed pudding or baked custard; fruit juice, apple or prune fool; toast; butter; cream; white cheese; digestive biscuits.
Tea.—Wholemeal bread and butter; spongecake; jelly; cream; tea.
Dinner.—Fish or egg dish; potato; baked custard or cold sweet; fruit juice or purée with cream; bread; butter; cheese; biscuits.

But such a diet does not help the bowel generally to do its own work and contract its muscular wall frequently. It is contractions which promote the health of the gut and prevent stagnation of faeces in the lumen and in the pockets. Even if only a little fruit purée and sieved greens can be borne they help to keep the bowels regular, aided by paraffin to grease the pouches and ensure that the motions are soft. Altering the flora of the gut by vegetable foods and *B. acidophilus* in milk also seems to do good. For the latter we use a freshly prepared culture in sterile milk of 200,000 bacilli to the cubic centimetre.

Attention to habit is especially important. The patient is told to take plenty of time, giving a little strain every third breath, but never to strain hard.

Many authorities advocate a regular aperient once or twice a week. My experience is that it is better to avoid, if possible, irritation by regular purges and to get the bowels working by the above-mentioned measures, reserving aperients for special needs. These may not arise if the patient has been helped by a period of daily observation and treatment.

The colon is washed out with normal saline every other day, for a time, but at low pressure, the funnel being not more than eighteen inches above the level of the anus. The fluid runs in just as well as, or often better than, at higher pressure, which may provoke spasm. In no case

should a diverticulous area be massaged. I have twice seen a quiescent area awakened into subacute and painful diverticulitis by a course of massage given in ignorance of the state with the object of curing constipation.

When diverticulitis is established the lavage is continued for longer, and in some cases permanently, at regular intervals. Enemas of 3 to 6 ounces of warm olive oil or liquid paraffin are sometimes useful, to be retained all night if possible. In some comparative tests we found that the saline washout was more effective in emptying barium out of the pouches than was the injection of warm paraffin. The salines on the whole are more likely than the paraffin to set up discomfort, and even lumbago pains, in those liable to them. Perhaps this is because they flush the diverticula more thoroughly and increase absorption or irritation for the time.

The general health must be maintained by regulation of work, exercise, and rest; and moderation in the use of tobacco. Alcohol is thought, as a rule, to be harmful in this as in other forms of irritability of bowel or bladder. Motoring is not well borne by many patients.

Results of Medical Treatment.

Repair after treatment of a *pre-diverticular bowel* is considerable, and our observations suggest that at this, its beginning, the disease can be arrested, or, at the least, its progress greatly retarded.

In the stage of *established diverticula*, since we have evidence that pouches empty their contents more readily after treatment—that is, paraffin, douching, and attention to general health—it may be concluded that stercolith formation is thereby retarded, if not prevented: also in most cases the symptoms disappear. It is probable that a transformation into larger pouches with wider necks may be induced.

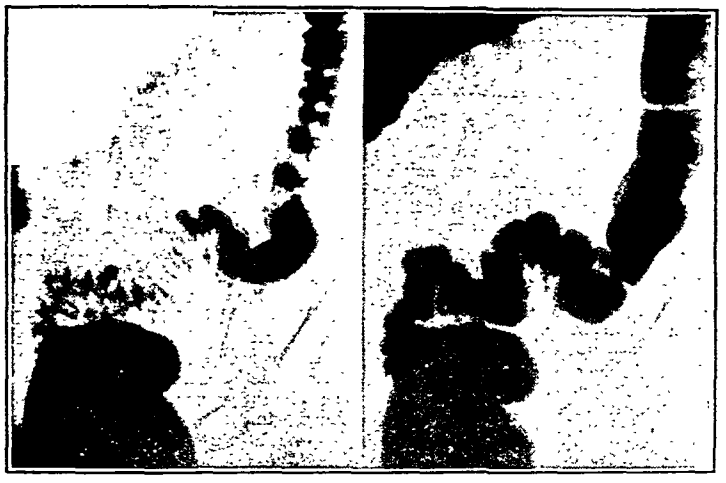

FIG. 3.—Showing the result of treatment. Subacute phase. On the left is a view of a piece of sigmoid in an inflamed state. There is new disease supervening on old. On the right is shown the same piece of bowel three months later, after steady treatment. The tumour could no longer be felt, the bowel having recovered to a comparatively normal state, with evidence of only slight induration.

In *subacute diverticulitis* it is remarkable how quickly the inflammation may subside with the above measures. The symptoms may be gone in a week. In the process of recovery the tenderness disappears and the tumour can be felt to become steadily less, and also more flexible when rolled very gently under the fingers. We have known a comparison of the radiograms after three weeks show that the lumen was restored almost to normal and the rigid area of bowel, as shown by serial films, much lessened. A more severe inflammation may yield to longer treatment (Fig. 3).

Operative Treatment.

Operation is needed, of course, for the accident of perforation of a pouch, which may occur, though uncommonly, at any stage after pouches are formed. At the end stage of diverticulitis, when obstruction, abscess, or fistula is present surgery is also often needed. As knowledge of the disease becomes wider these operations should be less frequent. In earlier cases most surgeons of experience recognize that operation often can and should be postponed or avoided by medical treatment (Moynihan,[1] Monsarrat[2]). But in some recent papers it is surprising to find that surgery is the only method of treatment advocated, an attitude which reveals a limited experience of the scope and pathology of the disease. But we are all in danger of taking too rosy a view of the method with which we are familiar. The standardization of work, in which one man uses one method and one tool all the time, may be good for output in manufactures, but until bodies and minds are standardized too it is bad for medicine and surgery.

Colostomy is sometimes needed for obstruction. When after this operation acute symptoms have subsided, the inflamed area usually gets steadily better and normal motions begin to be passed. After an interval it has been possible in certain cases to close the colostomy wound, the lower bowel resuming its function and with appropriate care remaining healthy. Operations suitable for dealing with fistula and septic complications will no doubt be described by those who follow me. We shall also discuss the pros and cons for an attempt being made at a radical cure by excising an area of bowel affected by diverticulitis. This operation should not be undertaken unless medical treatment as above described has been tried faithfully. If the symptoms are relieved entirely the treatment should be continued for several months, and progress estimated both by the clinical state and a barium enema. If the bowel is getting narrower, then operation should be considered before it becomes obstructed, with or without a preliminary or simultaneous caecostomy.

In a number of cases the disease is much localized, and these are favourable for excision, other things being equal. The situation of the lesion is of great importance. If the affected area is at the middle of the sigmoid loop there is often none too much room between it and the beginning of the rectum, even if the diverticulitic area shows a sharp margin between healthy and unhealthy bowel: but the margin is often far from sharp, and a second factor has then to be considered—namely, the state of the bowel above and below. In most cases there is diverticulosis of the neighbouring segments of bowel, especially above the lesion. Probably the existence of a few pouches does not prevent healthy healing, but if the disease is extensive and severe, it would, even if enough healthy bowel were found below the lesion, be necessary to excise a long piece above.

There is no justification for removing a piece of diverticulous bowel as such on the ground that it may become the seat of inflammatory changes, for, as above mentioned, it may not. Indeed, a man of 60 with multiple non-inflamed diverticula runs a greater risk of dying of other diseases than of diverticulitis. I trust that the removal of areas of bowel just because there is diverticulosis will not become a fashion like so many other fashions, both medical and surgical, which we have seen followed too far by the more active, if perhaps less thoughtful, of our profession in the last thirty years. I think of the overuse of many procedures, good in the right circumstances, but which, used unwisely, have done our credit much wrong.

I suggest that the following points are specially worthy of discussion: What are the difficulties of a differential diagnosis? How much evidence is there for regarding a non-diverticular and non-cancerous sigmoiditis as a separate disease? What is the best diet for chronic diverticulitis? Does the regular use of aperients do harm? How often is excision of a constricted area (*a*) practicable, (*b*) advisable? Have successful resections been done when the new junction has to be made at a

part of the bowel in which there are diverticula? Doubtless many others will arise.

Diverticulitis is a complaint that can be controlled if it is recognized early, though if allowed to take its course unchecked it becomes disabling and dangerous. It behoves us, therefore, as practitioners, to make ourselves as familiar as we can with the disease and especially with the early stages. It is hoped that such a discussion as that I have the honour to open now may do something more to forewarn and forearm the profession at large against its onset.

APPENDIX I.

At Ruthin Castle the colon had been observed with a barium meal or enema in 3,208 patients; 313 (roughly 10 per cent.) of these were the subjects of diverticulosis, and in 70 the disease had progressed to the stage of diverticulitis. Of these 70 patients, 54 were men and 16 women. The average age was 56; 21, rather less than one-third, of them were obese. There was an association of the disease with septic teeth, lumbar spondylitis, lumbago, sciatica, and apparently herpes of the nerves arising from the dorsal and first lumbar segments. Cancer was present in 4 cases—2 of the rectum and 2 of the sigmoid. This lent no particular support to the view that diverticulitis was a frequent cause of cancer.

Operations done on the advice of a physician at a convenient time were not dangerous. Of 5 so treated in this series there was no mortality, and the complaint was relieved in all. The heavy mortality quoted in the literature—12 to 25 per cent.—included those cases which had been unrecognized and untreated. Out of the 70 cases, 14 were now dead; 2 of these died from diverticulitis. One had vesical fistula and abscess; this patient had continued to take paraffin, but had omitted douching for three years. The other one died after a perforation. Twelve had died from other diseases. Fifty-two patients were known to have kept well as regards the bowel; of 5 there was no news.

Lantern slides were shown illustrating the development from diverticulosis to diverticulitis and results of treatment in diverticulitis.

APPENDIX II.

The nomenclature of this disease is cumbrous. I have consulted various authorities, including those who adhere to the B.N.A. nomenclature and those who do not. Whilst most condemn the terms we use and look for better ones, by others I am given to understand that the reform of medical terms is a domain where angels fear to tread. This angelic timidity is perhaps one reason which has led me to use all the old names. I may, however, mention that the Greek word σάκκος (Latin *saccus*) is, I am assured, as respectable etymologically as the word diverticulum, or more so. From it could be derived English words: sac, saccous or saccal, saccosis, saccitis, presaccal state. Dr. Cuthbert Morton pointed out to me that the use of these terms instead of diverticulum, diverticulous or diverticular, diverticulosis, diverticulitis, and prediverticular state would have saved nearly half a column in a recent article which occupied eleven columns of the *Lancet*.

DIVERTICULITIS OF THE SIGMOID.*

BY

WILLIAM J. MAYO, M.D., LL.D., F.R.C.S.(HON.),

ROCHESTER, MINNESOTA.

IT is singularly fitting that diverticulitis of the colon should be chosen as a subject for discussion at this meeting. The longest memory cannot recall a time when Lancashire has not spoken with authority on surgery of the colon, for the county has given to the profession the late Mr. F. T. Paul and the present President of your Association.

Diverticula of the colon were first described by Cruveilhier in 1849. The staff of Guy's Hospital has played an important part in drawing attention to the significance of the condition, since in 1857 Habershon, a physician to that hospital, published the first account of diverticulitis in English, while in 1885 Arbuthnot Lane described a specimen of the lesion obtained post mortem. In 1858 Sidney Jones reported a striking case of acute diverticulitis which resulted in a fistulous connexion between the bladder and the sigmoid. However, attention was not generally attracted to diverticulitis of the sigmoid until 1898, when Graser emphasized the frequency and significance of the disease. The first comprehensive treatise embodying both etiology and classification was brought out by Beer in 1904. This has been followed by papers by Telling, Drummond, Mummery, Hartwell, Brewer, Rogers, Mailer, and others. In 1907 Moynihan's classical paper appeared on its mimicry of carcinoma of the colon, and this deservedly received much attention. In 1907 Wilson, Giffin, and I reported five cases in which a portion of the sigmoid was excised for obstructive diverticulitis with the formation of tumour; these were the first instances recorded in which an actual demonstration of the pathologic change in diverticulitis was made during the life of the patient.

There are two types of diverticula of the colon—the acquired and the true. In diverticula of the acquired type the mucous membrane of the intestine pouches through small openings in the musculature at weak points in the wall of the colon, such as holes for vessels or defects of muscle. Such diverticula often contain small hardened faecal masses. This type is the one concerned in diverticulosis, in contradistinction to true diverticula of the congenital, traction, or pulsion types, in which all the intestinal coats cover the sac. The sigmoid is always involved in diverticulosis. If the entire colon is affected there is a gradual increase in the frequency of the diverticula from right to left. The diagnosis of diverticulosis now rests securely on radiographic evidence.

Records at the Clinic show a total of 1,918 cases of diverticulosis. Robertson's observations on our post-mortem service show that more than 5 per cent. of persons over 40 years of age have diverticulosis, and his data approximate as to frequency those based on *x*-ray evidence. Thus, in the period from 1924 to 1928 inclusive, 26,699 *x*-ray examinations of the colon were made for general diagnostic purposes, and in 1,574 of these (5.89 per cent.) diverticula were present. Only 16 of these 1,574 patients were less than 40 years of age. Of our 1,918 recorded cases of diverticulosis, active diverticulitis was present in 653 at the time the patients were examined. Inasmuch as in the earlier period, prior to 1916, only the cases of diverticulitis were recognized and properly recorded, these figures are of no value in establishing the frequency with which diverticulosis gives rise to diverticulitis. Statistics of the later period give over 12 per cent. of cases of diverticulosis resulting in diverticulitis, but for obvious reasons this is probably an overestimate. A study of the relative incidence of diverticulosis in men and women in this group of cases showed that 64 per cent. of the patients were men, 36 per cent. were women. As constipation is more common in women, these figures would seem to show that it is not an important factor in the causation of diverticulosis. Nor can much significance be attached to obesity as an etiologic factor, inasmuch as the percentage of patients who were under weight was about the same as that of those who were over weight.

CLINICAL FEATURES.

With rare exceptions, the type of inflammation of diverticula which we speak of as diverticulitis is confined to the sigmoid. The inflammatory condition usually is limited to one or several diverticula, but a considerable length of the bowel may be obstructed and greatly thickened from oedema and adhesive inflammation; thus a well-marked tumour in the lower part of the abdomen to the left of the median line often, if not usually, forms during the acute stage. Cases of the disease may be classified clinically into four groups.

GROUP 1: *Self-limiting Diverticulitis and Peridiverticulitis.*—The symptoms of acute diverticulitis are pain in the region of the mass, which is usually palpable, a moderate degree of fever, and gaseous distension. As a rule these symptoms are not severe, and although the temperature may be elevated one or two degrees, the patients are often ambulatory after the first day or two, and the tumour usually disappears in the course of a few weeks.

GROUP 2: *Diverticulitis and Peridiverticulitis with Formation of Abscess resulting in Entero-intestinal, Entero-vesical, Entero-cutaneous, and other Fistulas.*—This group includes those cases in which infections (either localized peritonitis with formation of abscess, or the results of infectious processes which

* *Read* in a discussion in the Section of Surgery at the Annual Meeting of the British Medical Association, Manchester, 1929.

connect the diseased sigmoid with the neighbouring intestine, the bladder, or the skin) lead to the necessity for surgical intervention. Rarely an infected diverticulum in the terminal portion of the sigmoid may be the cause of an abscess resulting in an intractable fistula in the posterior anal region, as pointed out by C. H. Mayo.

GROUP 3: *Diverticulitis Complicated by Obstruction of the Bowel.*—In acute diverticulitis the obstruction is the result of infection and oedema. Chronic obstruction is due to hyperplasia, adhesions, and angulation (the hyperplastic stenosing type). The conditions are practically identical with those in Groups 1 and 2, but the additional factor of obstruction in these cases is so serious a feature that it seems best to classify them independently. It is surprising, however, when the entire mass is dissected out and the diseased bowel laid open to find so little actual obliteration of the lumen of the bowel, and, unlike cases of carcinoma of the sigmoid, the obstruction is rarely complete.

GROUP 4: *Carcinoma Developing on a Diverticulum.*—This group is of great interest. In rare cases the carcinoma may have such a definite relationship to the diverticulitis as to make it reasonable to assume that infection and irritation by hardened faecal masses in diverticula might have been the cause of chronic irritation and precancerous change. Until recently the only known fact of significance in the etiology of carcinoma was its relation to chronic irritation. To-day the question of individual susceptibility to carcinoma is beginning to attract scientific attention. The term "precancerous" is used to denote certain cell changes taking place in areas of chronic irritation, which would be typical of carcinoma if found in connexion with invasion of the tissues.

It has often been pointed out that carcinoma of the sigmoid may progress very slowly. Cases have been reported in which colostomy was performed for the relief of obstruction due to supposed carcinoma; the patients lived for a number of years, and died from carcinoma of the sigmoid, a fact which was taken to prove that the condition had been carcinoma from the beginning, and that the natural course of the disease had continued for eight or nine years. This inference is unwarranted. In the Clinic we have operated on several cases of this type, and on resection of the growth have found carcinoma developing in a sigmoid in which the results of an ancient deforming type of diverticulitis were present. In tracing the early histories of the patients it could be seen that the diverticulitis had been present from the beginning of the illness, and that the malignant change had been a more recent development.

In reviewing a series of specimens of sigmoid which had been resected for supposed carcinoma at the Clinic Wilson found that three, resected years ago, before all specimens were subjected as a routine to microscopic examination, showed diverticulitis and not carcinoma. The possible association of carcinoma with diverticulitis leads to the conclusion that when a tumour appearing to be diverticulitis, but without acute symptoms, is found in the sigmoid or colon, and especially if the tumefaction subsides only partially and then continues as a chronic mass causing more or less marked symptoms, carcinomatous change is to be suspected, but the relation between the two remains conjectural. Some idea of the relative frequency of the two conditions in the sigmoid may be obtained from our own figures. In the stated period we dealt with 653 cases of diverticulitis and 1,259 cases of carcinoma.

The distinction between diverticulosis and carcinoma of the sigmoid can usually be demonstrated by radiological methods. These methods will usually show also a carcinomatous change in a diverticulous area of the sigmoid, but if diverticulitis is present this diagnostic agent cannot be used so freely during the more acute stages of the process.

SURGICAL TREATMENT.

The treatment of diverticulitis of the sigmoid depends on many factors. In acute cases, especially if the patient is old, obese, and a poor risk for operative procedures, it should be tentative. In our series of 653 cases operation was performed for this condition in 26.18 per cent. If the infection goes on to the formation of abscess the pus should be evacuated, instead of waiting for its spontaneous discharge, as the latter course tends to lead to the formation of a fistula, with its attendant evils. If more radical treatment appears to be necessary to effect a cure, it can be postponed to a later and more favourable time. If acute obstruction results colostomy should be performed as close to the obstructed point as is convenient, so that at a subsequent operation the stenosed portion of the sigmoid and the colostomy opening may be excised simultaneously through the same incision, or, as advised by Stiles and by Burgess, caecostomy may be performed for temporary relief and the radical operation performed later if it becomes necessary. In other cases colostomy may be resorted to for temporary relief, and the opening in the colon closed later, if the infective process retrogresses spontaneously sufficiently to restore the lumen of the colon.

If the patient comes for relief of an internal fistula, especially one communicating with the bladder or with another part of the intestinal tract, a serious problem confronts the surgeon, the operative risk being proportionate to the number of internal fistulas and to their situation. I know of no more trying operations than some of this character. In several instances I have dissected out multiple entero-intestinal fistulas communicating with the bladder, and have carefully sutured the bladder and each intestinal opening; after several days leakage to the surface has followed the line of drainage, with temporary discharge of urine and faeces. However, these wounds have eventually healed. A very excellent technical step in such cases was first suggested, I believe, by C. H. Mayo. This consists in completely separating the involved sigmoid from adherent intestines and bladder, and, after suturing the fistulous openings, or resecting the diseased segment of bowel, in bringing the omentum into the operative field. An opening is made in the omentum through which the sutured portion of the sigmoid is brought to the peritoneal surface of the abdominal incision, where it is attached by a few sutures. The omentum is thus thrown between the defects in the colon, bladder, and adherent intestines, and if leakage occurs later a safe exit is provided.

CONSIDERATIONS ON THE ORIGIN OF ACQUIRED DIVERTICULA OF THE SIGMOID.

The romance of medicine lies in inductive philosophy, in which to-morrow is the great day. Yesterday furnishes the deductive philosophy, which acts as a compass to keep our directions true.

In mammals the testis is the primitive procreative organ, and because of its long heredity it is relatively free from disease; the ovary, secondary to the testis, is a more recent acquisition, which has not yet achieved the same resistance. So, too, the sigmoid, a convenient storage organ but of more recent development, has not yet achieved the stability of the primitive small intestine. The right half of the large intestine is derived from the midgut, and in the embryo has the same type of epithelium as the small intestine and carries on an absorptive function. The sigmoid is derived from the hindgut, and has relatively little absorptive function. By reverse peristalsis derivatives of the food end-products are returned for further elaboration and absorption until the faecal stage is reached.

Certain recent investigations by Alvarez and his colleagues have shown the influence of food products on mass. Among the various types of food which form a mass, such common articles of diet as potatoes and milk form a relatively large mass, whereas red meats induce a large amount of bacterial action. Three-fourths of the peoples of the world eat rice for carbohydrate, and more or less fish for protein. Rice not only has a high calorie content, but also it liquefies and forms only a very small mass; such articles of diet as fish also form a small mass. It would be interesting to know whether diverticulitis is as common in the rice and fish eating countries as it is in the potato and red meat eating countries.

To one who has watched through the fluoroscope the spastic colon struggling with a barium content, it is not difficult to understand how and why pits form in the areas of weak musculature of the colon and along perforations made by its blood vessels. Again, now that we are getting new light on the sympathetic nervous system, which acts as a brake on intestinal progress, we see a possible explanation of some of the phases of the development of diverticula. Learmonth and Markowitz have shown that after section of the inhibitory nerves to the colon of the dog, in certain cases, a barium meal may show appearances suggestive of early diverticulosis.

Speaking picturesquely, one notes various types of control over the vegetative functions—for example, the linking up of non-striated muscle with the nodal system and with the internal secretions so largely instrumental in carrying on gastro-intestinal functions. These controls are shown in the occurrence of intestinal peristalsis once or twice in each minute and intestinal contractions eighteen or twenty times in each minute, the latter movements serving as a motor pump to propel venous blood in the portal system to the liver. All of these forms of stimulation are linked with the sympathetic nervous system, and through the sympathetic ganglions with the central nervous system. Our knowledge of this interrelationship we owe to the fundamental work of Gaskell and Langley.

The work of Hunter and Royle has stimulated fresh surgical interest in the sympathetic nervous system. In this field Adson and his associates have been able to relieve megacolon, which so closely resembles the dilated oesophagus in cardiospasm, by removal of the lumbar sympathetic ganglions and their communicating branches. The operation effects its purpose probably by leaving the sacral sympathetic outflow, which is motor to the distal part of the colon, in sole control of this part of the bowel. Adson and his co-workers also have brought about marvellous relief in Raynaud's disease, in certain types of contraction of the blood vessels of the extremities leading to gangrene, and in certain types of arthritis, by removal of the appropriate sympathetic ganglions and their communicating branches.

SANOCRYSIN TREATMENT OF PULMONARY TUBERCULOSIS.*

BY

B. R. CLARKE, M.D.,

MEDICAL SUPERINTENDENT, FORSTER GREEN HOSPITAL, BELFAST.

SANOCRYSIN is an organic salt of gold, and was first used for the treatment of tuberculosis in man in 1923, after several series of experiments on animals by Professor Moellgaard. The exact action of sanocrysin on tubercle bacilli or tuberculous tissues is still a subject of controversy. It is now more than four years since this treatment was introduced into the British Isles, and it should be possible to form some estimate of its value. From the clinical point of view there are a number of questions which it is important to answer: (1) What are the dangers of sanocrysin treatment? (2) What is the correct dosage? (3) Has sanocrysin any value in the treatment of pulmonary tuberculosis? (4) What type of case is likely to benefit from the treatment?

In the following remarks an attempt will be made to answer these questions from the records of the 102 patients discharged from the Forster Green Hospital after sanocrysin treatment between 1925 and 1928. All these patients had tubercle bacilli in the sputum, and a high percentage of them were of the exudative type.

Professor Moellgaard's original experiments convinced him that sanocrysin was well tolerated by healthy mammals; rabbits, goats, calves, and monkeys were injected intravenously with 3 cg. per kilo of body weight without serious results. It had no injurious effects on the kidneys of healthy calves and rabbits in doses of 2 cg. per kilo of body weight, while larger doses in calves caused oedema of the epithelium of the tubuli contorti. Transient albuminuria (three to four days) sometimes followed the early injections, but by graduating the dose a tolerance could be produced. Symptoms, such as diarrhoea, loss of weight, and fever, did not appear after the injection of sanocrysin in healthy calves. The result of an injection of sanocrysin was quite different in a tuberculous calf. Often the animal died of shock in forty-eight hours, while severe albuminuria, haematuria, diarrhoea, and loss of weight occurred if the animal survived long enough for observation.

There has been much discussion on the interpretation of these reactions in tuberculous animals, which Professor Moellgaard attributed to auto-inoculation, resulting from the destruction of tubercle bacilli in the body by sanocrysin. He solved the difficulty of treating the calves by the use of a serum, and then produced some curative results in experimentally infected calves and also in naturally infected monkeys. So far as I know, the serum is not used now in conjunction with sanocrysin treatment in man. In proportion to body weight, the doses employed in these experiments were rather larger than any used now in the treatment of human tuberculosis; also the intervals between the doses were shorter. It is, however, most important to consider the body weight in each individual case, in order to avoid the danger of overdosage.

The elimination of sanocrysin is effected mainly through the kidney, and it has now been shown by McCluskey and Eichelberger that at least thirty days are required for all the gold to disappear from the urine. The same observers found that doses of 2 cg. per kilo of body weight had rather marked effects in normal dogs, causing vomiting, diarrhoea, and albuminuria. Studying mice, S. Kimosa found that the tolerance was raised by increasing the dose gradually. J. Frandsen found that sanocrysin was not injurious to the kidneys of normal rabbits.

To summarize our present knowledge of the toxicity of sanocrysin, it appears that the drug in a pure state is not injurious to healthy mammals in doses of 1 to 1.5 cg. per kilo of body weight. Tolerance is increased by graduated dosage, provided there is a sufficient interval between the doses. The kidneys are mainly responsible for its elimination, which takes place much more slowly than was first supposed. It is, moreover, much more liable to damage the tuberculous organism than the healthy one.

The question of dosage has occupied the attention of all who are employing sanocrysin. By decreasing the dosage too much one may fail to get positive results. On the other hand, the dosage which was originally employed in Denmark and the British Isles is undoubtedly excessive, and exposes the patient to grave risks. The original plan was to give half a gram and follow this by a gram two or three days later. If the patient survived these initial doses, one gram was given weekly five or six times. The great majority of deaths resulting from sanocrysin were associated with this high and intensive system of dosage.

On the other hand, many of the patients who were able to tolerate these high doses at short intervals made a remarkable improvement, and some have remained well for the past four years. Hyperpyrexia, intense focal reaction in the lungs, haematuria, albuminuria, anuria, and jaundice were among the symptoms which were liable to appear, usually after the second large dose of sanocrysin. In considering the question, it is important to remember two facts to which reference has already been made: (1) The complete elimination of sanocrysin from the body takes a long time. (2) By graduating the dose one is able to create a tolerance, and ultimately large doses may be injected without causing any severe symptoms. A system of graduated dosage has now been generally adopted, with lengthened intervals between doses.

In afebrile patients it is safe to begin with 0.25 gram, and to increase the dose by the same amount in arithmetical progression until 0.75 gram is reached, which dose may then be repeated four or five times. Usually this scale of dosage will be tolerated well by patients weighing from 8 to 10 st. With patients who are over 10 st. the final dose may be increased to 1 gram, and in very light or emaciated patients 0.5 gram should be regarded as a maximum dose. The interval between the early doses should be about a week, or longer if the symptoms of reaction have not subsided. The interval between the larger doses should be ten days, or even a fortnight. In the treatment of febrile patients one may begin with 0.05 or 0.1 gram, and increase the dose very slowly, if the injections appear to be doing good. Some patients are unable to tolerate sanocrysin, even in small doses, and in 16 per cent. of the cases in my series the treatment was abandoned when less than 2 grams of sanocrysin had been

* Read in opening a discussion in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Manchester, 1929.

administered. Five of these were very seriously ill, and treatment was stopped because of the progress of the disease, not on account of any reaction. The reasons for stopping treatment in the others were as follows:

Diarrhoea	7
Prolonged albuminuria	1
Focal reaction	1
Intercurrent tonsillitis	1
Fistula in ano...	1

Two of the patients underwent a full course of sanocrysin treatment subsequently, with satisfactory results.

There has been discussion as to whether it is advisable to give several courses of sanocrysin. No doubt others will deal with this point, but my experience of second or third courses is small. I have an impression that a second course should follow at a short interval, say a month or six weeks, and that if a second course is considered necessary exercise should be strictly limited between the two courses.

Complications.

Up to the end of 1928, 102 patients had been discharged from the Forster Green Hospital after sanocrysin treatment. Five patients were treated by the original method with large doses, and the remaining 97 patients were treated with graduated doses. By good fortune no serious accident occurred in the course of the treatment of the first 5 patients, but 3 of the 5 had diarrhoea, 3 had a scarlatiniform skin eruption, 4 had vomiting after the injections, and all of them showed a loss of weight during and after treatment, varying between 1½ and 16½ lb. In the 97 patients who were treated by graduated doses complications occurred less frequently. The following table illustrates the fact that complications have been less frequent in the later cases of the series.

	Cases 1-50.	Cases 51-102.	Total.
Marked febrile reaction	11	15	26
Slight febrile reaction	24	19	43
Prolonged febrile reaction	1	3	4
Albuminuria (transient)	15	11	26
Albuminuria (marked)	22	9	31
Vomiting	17	5	22
Diarrhoea	10	4	14
Loss of weight	21	15	35
Dermatitis	8	4	12
Neuritis	1	2	3
Stomatitis	13	2	15

There is little to add here to what has been written already about the complications. There was one case of persistent albuminuria, apparently due to permanent damage to the renal tissues. Stomatitis was noted in 15 patients, 13 of whom were males. Several of the cases were due to smoking, contrary to instructions.

The most serious complication which has arisen has been prolonged fever, with a spread of the disease in the lungs. This occurred four times in the series of 102 patients treated, and 3 of the patients died within a short time, the fourth making a good recovery after seven weeks of fever. This prolonged reaction has been noted also in 2 patients who are not included in this series, as they were still in hospital at the end of 1928. In the 2 latter cases the reaction has subsided, and there is now improvement. The 6 patients who showed these prolonged severe reactions were all "advanced" cases, according to the classification by signs and symptoms. They were all cavity cases, with considerable toxaemia, as shown by temperature and pulse rate. The reaction usually occurred towards the end of the course of injections, and in 4 of the cases it was probably due to a cumulative action of the sanocrysin. Of the other 2 cases, one, which recovered, developed a pleural effusion as a complication of artificial pneumothorax treatment after the second injection. The other, also an artificial pneumothorax case, had a rupture of the lung and died four weeks later.

It is obvious that the dangers and troublesome complications of sanocrysin treatment are not to be ignored. It would not be justifiable to continue such a treatment unless there was a definite probability of obtaining substantially better results than by conservative methods.

Beneficial Effects.

Where sanocrysin is well tolerated there are beneficial results, which follow in a high proportion of the patients. In the majority of the cases tubercle bacilli have disappeared from the sputum. Often, but less constantly, there has been a rapid clearing up of the *x*-ray picture, heavy cottony shadows being replaced by well-defined markings, and by signs of contraction of the diseased areas in the lungs. When these changes are marked the absence of bacilli from the sputum is likely to persist, but when the *x*-ray picture shows little improvement tubercle bacilli will reappear in the sputum. The changes in the *x*-ray picture which follow sanocrysin treatment have been described minutely by several Continental physicians, and the phrase "sanocrysin lung" has been coined to describe the shrunken fibroid lung often observed at the conclusion of a course of sanocrysin. This contraction of the lung is most likely to occur in cases where the disease is lobar in distribution, and in other exudative types of disease resolution may take place without radiological evidence of much fibroid change.

The effect on fever which has not yielded to prolonged rest in bed is often very marked, and after a few injections the temperature may become normal. This improvement is followed later by a diminution of the pulse and respiration rates.

The physical signs often show a rapid improvement. On auscultation it is found that the areas of moist crepitations have cleared up, being replaced by diminished breath sounds. If the improvement continues, harsh breathing and prolonged expiration become marked, and crepitations are not to be heard, even after cough.

Besides objective signs of improvement, there is a striking change in the aspect of the patient when the treatment is successful. The phthisical facies disappears, and the flabby chest muscles become rounded and firm. Lastly, so far as it is possible to judge in the short period of four years, patients treated with sanocrysin have a lower mortality rate than untreated patients.

All tubercle bacilli positive cases discharged from Forster Green Hospital from July 1st, 1925, to December 31st, 1928, were traced in the spring of 1929. These patients were classified in three groups, according to the severity of the symptoms on admission. In the moderate group 80 per cent. of those treated with sanocrysin are alive, and only 63 per cent. of those who did not have sanocrysin treatment. In the advanced group, 58 per cent. of the sanocrysin-treated cases are alive, as compared with 30 per cent. of untreated cases.

Results of Sanocrysin Treatment.

In considering the results I have included all cases in which the treatment was attempted. Of these, 19 were very seriously ill when treatment was begun, and 13 of these are dead, although marked temporary improvement occurred in 8 of them. Of the 6 surviving patients in this group, 2 had a spontaneous pneumothorax, complicated by a mixed infection, and 2 had artificial pneumothorax.

An attempt has been made to analyse the results in the remaining 83 cases. First they were divided into three groups as shown in the following table.

	Alive.	Dead
1. No evidence of cavity	21	3 = 12.5%
2. Radiological evidence only of cavity ...	29	6 = 17%
3. Clinical evidence of cavity	17	7 = 29%

The result was more remarkable when an attempt was made to classify the cases into "exudative" and "fibroid" groups, according to the *x*-ray picture.

	Exudative.		Fibroid.	
	Alive.	Dead.	Alive.	Dead.
No cavity	14	3	7	—
Cavity *x*-ray evidence only	18	5	11	1
Cavity clinically	7	7	10	—
Totals	39	15	28	1

There has thus been a heavy mortality in the exudative group, although many of them did well while under treatment. But I believe that the results in exudative cases could be improved on, if treatment were prolonged over a period of several months. Frequent *x*-ray examinations are necessary in such cases, and the patient should be kept at rest as long as any exudative foci can be seen on the *x*-ray film.

Possibly it may prove to be best to give several courses at short intervals. In any case, if active disease is present after sanocrysin treatment, artificial pneumothorax or phrenic avulsion should be considered, even if the temperature and pulse rate are normal. I think also that some exudative cases with cavitation should have a period of rest and tonic treatment before trying sanocrysin, which might be employed when the limit of improvement has been reached.

In the fibroid group, however, the results have been more satisfactory, as there has been only one death among 29 patients. It might be suspected that these patients would have done equally well without sanocrysin, but most of them had the treatment because they had failed to respond to routine measures. Of this group, 55 per cent. were discharged without tubercle bacilli in the sputum, as compared with 43 per cent. in the exudative group. Excluding 10 "cavity" cases, 72 per cent. of the fibroid cases were without tubercle bacilli on discharge.

Tuberculosis of the larynx was present in 8 cases of my series, and I do not think it contraindicates sanocrysin treatment, as the laryngeal condition usually improved, and 6 of the 8 cases are alive.

Cachexia, intestinal tuberculosis, and disease of the kidneys are contraindications.

It is often advantageous to combine sanocrysin and collapse therapy, especially in cases where there is widespread disease of one lung, with some active trouble in the better lung. If the case is acute, and the lung tissue is breaking down rapidly on one side, it will probably be necessary to collapse the worse lung immediately and try sanocrysin afterwards.

In another kind of case, when the patient has passed through the acute stage and shows some resistance, I have found it more satisfactory to give a long course of small doses of sanocrysin first, and to try artificial pneumothorax later.

When the disease is almost entirely unilateral, and collapse therapy is clearly indicated, I think sanocrysin should not be employed; later, if fresh foci of disease develop in the functioning lung, it may be of service. In my series 19 patients had artificial pneumothorax treatment, and satisfactory collapse was attained in 7, all of whom are alive at the time of writing. The collapse was only partial in 11 patients, and 5 of these are alive.

There are two types of pulmonary tubercle in which I think sanocrysin may be of value. One is the early exudative case in which the disease in the lungs is severe or widely spread, but in which there is some evidence of resistance. The other is the predominantly fibroid type of disease, when symptoms and tubercle in the sputum persist after several months of sanatorium treatment. In the exudative case I think it is important to begin sanocrysin treatment as soon as possible. In the fibroid case sanocrysin should be withheld until sanatorium treatment has had a trial.

When there is disease of long duration, combined with an exudative *x*-ray picture, sanocrysin treatment is not free from danger, but in such cases it may be possible to combine it successfully with artificial pneumothorax.

In judging the results, it should be remembered that the type of pulmonary tuberculosis seen in hospital patients in Ireland is commonly severe.

I have been encouraged to persevere with sanocrysin treatment by the opinions expressed by my colleagues in Belfast and elsewhere. Certainly it is not a cure for tuberculosis of the lungs, but it is a valuable aid to treatment, if used with caution and discrimination.

ASBESTOS DUST AND THE CURIOUS BODIES FOUND IN PULMONARY ASBESTOSIS.*

BY

W. E. COOKE, M.D., F.R.C.P.ED., M.R.C.P.LOND., D.P.H.

(From the Pathological Department, Wigan Infirmary.)

ASBESTOS was woven into cloth before the time of Herodotus 450 B.C., but the history of the industrial disease pulmonary asbestosis dates only from A.D. 1900.

In 1899 a man was admitted to Charing Cross Hospital under the care of the late Dr. H. Montague Murray. The patient was suffering from pulmonary fibrosis of obscure origin. He had worked for ten years in an asbestos factory, and his occupation was suspected as being the cause of death, which occurred in 1900. The case was not published, but Dr. Murray, in his evidence before the Departmental Committee on Industrial Diseases in 1906, referred to the presence of spicules of asbestos in sections of the lungs.

The next case, and the first published, was recorded in 1924. The clinical history and histological appearances have been the subjects of papers in the *British Medical Journal* (1924–27), and in the *Journal of the Royal Microscopical Society* (1927). The findings upon which the diagnosis of pulmonary asbestosis was made in that case, and the results of further work on the curious bodies that have been found in the lungs in all necropsies in the disease are the subjects of this paper.

Asbestos and Asbestos Dust.

Asbestos belongs to the pyroxene or hornblende group of minerals, and is classed with syenite, granite, and porphyry. I scarcely need remind you that the igneous rocks were originally silicate solutions—compounds of silicic acid with earthy bases. Under certain physico-chemical conditions hornblende and serpentine pass into fibrous varieties and are then given the technical name "asbestos."

The infinite varieties of asbestos differ in their chemical constitution and physical characters, but I propose to deal with one type only—chrysotile—the average composition of which is:

Silica	40.87 per cent.
Magnesia	41.50 ,,
Ferrous oxide	2.81 ,,
Alumina	0.90 ,,
Water	13.55 ,,

The iron content may be important. It will be interesting to see whether the effects of the iron-free dusts of some Italian, Arizona, Finland, and Chinese asbestos are the same as in chrysotile workers.

Microscopically, chrysotile fibre consists of colourless refractile translucent strands, but intermingled with the fibre are masses of black angular particles, brown particles of all shades from light yellowish-brown to deep golden brown, and particles the colour of sapphire blue. The dust generated during the process of manufacture consists of fragments of fibre and translucent spicules split off from it.

* A paper read in a discussion in the Section of Occupational Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

These spicules are of varying lengths and thicknesses, some of them being beyond the limits of resolution and ultra-microscopic. The dust contains also the black, brown, and blue fragments seen in the raw asbestos. The colourless translucent particles and the brown and blue particles of the dust are refractile by polarized light. The black particles are biotite and magnetite, and do not transmit light. These iron-containing minerals are responsible for the varying percentages of iron in different specimens of asbestos, and, as would be expected, the dust containing the greater number of these black particles has the greater iron content. Microscopically, the finished woven article contains very few black particles, whereas the dust from the carding room is grey in appearance and contains them in abundance. The iron content of chrysotile, the finished article, and the dust is as follows:

Chrysotile: iron (as ferrous oxide) ...	2.81 per cent.
Finished article: iron (as ferrous oxide)	0.1 ,,
Dust from carding room: iron (as ferrous oxide)	18.4 ,,

In addition to the angular pieces a fine black granular dust is generated during the process of manufacture.

Asbestos Dust in the Lungs.

Sections of lung and the results of digestion of the lung with trypsin show an enormous amount of fine black granular dust, much of which is carbonaceous. In addition there are two striking features. The first is the almost complete absence of the very fine translucent spicules of fibre which make up the great proportion of asbestos dust in factories. This point will be referred to later. The second feature is the presence of large fragments varying in length from 10 to 360 microns. They are found in fibrotic and necrotic areas, singly and in groups. The particles are so large—masses of them are seen in some sections—that they must have occluded small bronchi and resulted in fibrosis of the surrounding area with, later, necrosis.

Comparing these large particles in the lung with those found in asbestos dust the close resemblance in sizes, shapes, and colours is apparent. There are the same black, blue, brown, and translucent fragments. In fact, it is easy to take each single particle from the lung and immediately find its brother in a slide made from the dust.

The question I had to answer with regard to the 1924 case was, "Did the deceased's occupation cause or contribute to her death?" Upon the foregoing evidence one answer only was possible.

The Curious Bodies found in Pulmonary Asbestosis.

In addition to the fine granular dust and larger fragments of asbestos, sections of the lungs show curious bodies, some of which are illustrated in Figs. 1–5. They are found in alveoli, bronchioles, fibrous and necrotic areas, and in phagocytes, in sections of both lungs. If a portion of lung be teased and extracted with water, or digested with trypsin, or, as Professor Stewart pointed out (1928), a smear is made from the cut surface of the fresh lung, these bodies are seen in myriads. The larger bodies measure from 20 to 100 microns or more in length, are of a golden brown colour, and some are shaped as seen in the illustrations. They may have single clubbed ends or appear as elongated dumb-bells, some as filaments, while others suggest a series of discs. Single coccal and spore-like forms, and aggregations of these, and streptococcal forms are not uncommon, and the colour varies in the smaller types from a very pale yellow to a yellowish-brown. The bodies do not stain with any of the aniline dyes, but, in chrysotile workers, give the Prussian blue reaction for iron in varying degrees of intensity. These curious bodies have been found in every necropsy in pulmonary asbestosis, and the problems we have to decide are, first, what the bodies are, and secondly, whether they are diagnostic of asbestosis. It would be unprofitable to retrace all the steps which led down the many by-lanes during the course of the work, but I might mention a few pertinent details of interest.

Professor Stewart suggested to me that a better method than simple extraction of the lungs with water or saline would be to digest portions with trypsin. During this process it was found that if the specific gravity was kept about 1070 the black dust and larger fragments of asbestos, as well as the partially digested lung tissue, sank to the bottom of the tube. By decanting the apparently clear supernatant liquid, centrifugalizing, neutralizing, and washing the deposit, the curious bodies could be obtained in a pure state. This was done, and sufficient material for *x*-ray examination obtained. The bodies were attached to a hair with gum and subjected to a seven hours' exposure by Professor Bragg's method. If the bodies were mineral the *x*-ray film would have shown a definite translatable atomic pattern. The films, however, did not do so, and we were then able to exclude the suggestion that the bodies were altered asbestos fibre. The result definitely pointed to the greater proportion of their composition being of non-mineral origin.

The bulk of the curious bodies is soluble in strong acids and alkalis, and if solution be observed under dark-ground

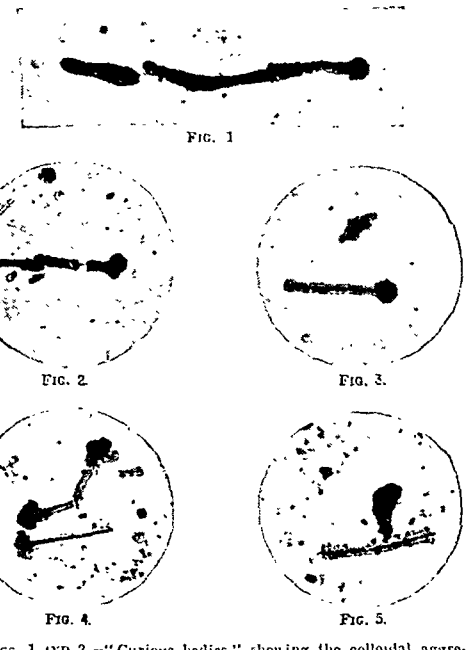

FIG. 1

FIG. 2

(Photomicrographs by C. T. Hill and W. E. Cooke.)

illumination their bases are seen as extremely fine spicules, some of which, by transmitted light, would probably be invisible.

Under a dissecting microscope it is possible partially to fracture the larger bodies and to show a central fine core, as in Figs. 1 and 2.

I have mentioned that the greater portion of asbestos dust consists of slender translucent fibres. In sections and extracts of the lungs there is a remarkable paucity of these fine spicules. The end-results of digestion show the fine granular dust and the large black, blue, and brown particles, and what appear to be pieces of quartz. Relatively few fine spicules are found, but curious bodies of all descriptions are present in enormous numbers.

All these facts lead us to imagine the bodies to consist of central nuclei of asbestos spicules upon which colloidal aggregates of blood proteins, *plus*, possibly, soluble fractions of asbestos, and in the case of chrysotile workers an iron salt, have been adsorbed and moulded by currents in the bronchi and alveoli.

Occasionally biotite fragments into fine black spicules, and if our reasoning be correct, some at least of the millions of curious bodies should show a central core of this mineral. Figs. 3, 4, and 5 illustrate this condition, and are, I think, the final proof of our theory.

The method of formation would appear to be as follows. The fine spicules of asbestos cause, by mechanical action on the bronchioles and alveoli, either minute extravasations of whole blood, or serous exudates, which envelop them. Solution of any soluble fraction of asbestos takes place. The total amount of asbestos that is soluble must be extremely small, as proved by the *x*-ray pattern of the curious bodies, but in the case of chrysotile workers some solution is suggested by the free iron reaction. We must remember, however, that the Prussian blue reaction may be due to the iron of haemoglobin. Any surface in contact with a colloidal solution may act as an adsorbent, and in the present case the fine spicules must be considered to do so. Interaction between the soluble fraction of chrysotile and plasma proteins takes place, syneuresis occurs, and, with the loss of water, the adsorption is rendered irreversible. The adsorbent is permanently ensheathed with stable colloidal aggregates which become moulded into the familiar shapes by alveolar and bronchial currents.

Some support of this is adduced by the fact that micro-organisms adsorb colloidal material in the presence of blood serum and colloidal asbestos. Staphylococci so treated appear as large round yellowish-brown discs, and in the process their property of staining with aniline dyes has been lost. The organisms coalesce and form masses, and I think it probable that some of the coccal and spore forms of the curious bodies are similar organisms.

Finally, the answer to our second question must be found. Are the curious bodies diagnostic of pulmonary asbestosis? Asbestos is unique among the minerals in being fibrous, and the dust generated during the manufacturing process is also unique. As can be imagined from the formation of the curious bodies, there is no reason why any fine spicule of mineral should not have colloidal matter deposited around it and become moulded into a curious body. But, as no other mineral dust is fibrous, this occurrence must be so rare as to be negligible from a diagnostic point of view. The conditions which, apparently, must obtain for the formation of the curious bodies are the presence of plasma proteins and fine spicules of difficultly soluble material. These conditions are ideally found in asbestos workers, and for this reason I believe the curious bodies, if found in any numbers, are pathognomonic of pulmonary asbestosis.

I must express my gratitude to Dr. S. A. Henry and Dr. E. R. A. Merewether of the Home Office for their stimulating interest in the work, and for providing me with many specimens of asbestos, and to Mr. T. H. Byrom, F.I.C., and Mr. J. A. Darbyshire, M.Sc., for their invaluable assistance in the chemical and physical side of the work.

CLINICAL ASPECTS OF PULMONARY ASBESTOSIS.*

BY

A. C. HADDOW, M.B., CH.B.,

LEEDS.

History.

DURING 1926 Dr. Ian M. D. Grieve, who was then with me in general practice at Leeds, drew my attention to the fact that several patients under our care of late with chest troubles were asbestos workers, and we agreed that they exhibited features sufficiently in common to justify investigation of what seemed an uncommon type of pneumonoconiosis. We accordingly examined every asbestos worker who came our way, some fifteen in all, and had most of these radiographed. Then, in March, 1927, a female patient with long-standing disease died in hospital, and Dr. Grieve attended the post-mortem examination. With Dr. A. L. Taylor he examined the sections of fibrosed lung, and found a remarkable condition which Professor Stewart recognized as similar to the case described by Dr. Cooke in 1924.

Sir Thomas Oliver came to see our cases, and he described the clinical findings before this Section of the *British Medical Association* at Edinburgh in 1927. The two patients he reported on (both women) have since died, one in March, 1928, and the other in February of this year. One male patient died in March, 1928, and it was the certification of this case as death from "broncho-pneumonia, secondary to chronic asbestos poisoning, causing pulmonary fibrosis," which brought about the publicity of a coroner's inquest and official recognition of this disease.

Fatal Cases.

Of these four fatal cases the average age at death was 41, and the average years actually spent in the factory were under twenty, all in asbestos mattress-making for most of the time. The male patient had worked until two days before death (on a light job), but the three others had been incapacitated for an average of two and a half years (three years and five months, two years and five months, and one year and ten months). Only in one of them had tubercle bacilli been found in the sputum. She was one of those reported by Sir Thomas Oliver, and at her own request no necropsy was held.

I cannot personally trace any other death of an asbestos worker in my practice except that of a woman who died of perforated gastric ulcer in Leeds Infirmary, and whose lungs were examined by Dr. A. L. Taylor, with positive findings, two years ago. No death had ever been traced to asbestos dust in Leeds until the present series, and the only asbestos workers recorded by the medical officer of health for Leeds as having died of phthisis were found to have worked at a gas-mantle factory where asbestos is not employed in any department. I know that many workers had drifted away from the asbestos factory because they believed it was unhealthy, whilst many women had ceased work to attend to their homes, and any fibrosis present would readily be overlooked in later years when death overtook them.

Advanced Cases.

In practice these workers do not call for much attendance until they reach the stage of total incapacity. Until then they are naturally more prone to chest troubles during the winter months, and are sometimes unfit for weeks at a time, but at the present moment I have only four cases under treatment. These are all permanently incapacitated. They are all women, and are fairly well at present, though they were very ill in February and March. Three of them have been away from work for eighteen months and the fourth for four and a half years. They were all in the mattress department. Their average age is 35, and their average of years spent in the factory is fourteen, dating back to their teens. They average three children apiece, which accounts for most of the time lost from work. The children are healthy enough.

Clinically, they all suffer from shortness of breath on exertion, have cough without expectoration, are lean, although not losing weight at present, and complain of anorexia with resulting weakness (for in Yorkshire one is only as strong as one's appetite). Pain is variable, and occurs from time to time with signs of localized pleurisy. Night sweats are absent, and there has been no haemoptysis. No tubercle bacilli have been found. Their hearts are normal, with a pulse rate approaching 90 at rest. The average full range of chest expansion is only one inch in the upper thorax and even less around the lower ribs. On percussion there is always some dullness at both bases, and usually over the lower lobes generally. The breath sounds are diminished over the same area, and the voice sounds are usually well conducted. The respiratory murmur in the upper lobes is broncho-vesicular. Friction sounds can be heard at the bases and sometimes in the flanks. Moist rales and crepitations are for the most part absent *now*, but were abundant at the bases during the winter. These exacerbations have a serious bearing on the cases, and it will be noted that all the deaths have occurred at the end of winter.

Onset of Symptoms.—It is very difficult to ascertain the date of onset of symptoms, but the patients generally believe it was after five years of work. Depending as it does on so many factors, it must be extremely variable.

* Read in the Section of Occupational Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

Our earliest clinical diagnosis is also in the neighbourhood of five years of work.

X-ray Findings.—Excellent radiographs of these four advanced cases were taken for me by Dr. Rowden recently. Exposure was for two-fifths of a second. All the chests showed abnormal radiolucency and marked limitation of diaphragmatic movement. The radiographs show this translucency above the level of the ninth rib posteriorly and the fourth rib in front. Below that level, roughly, in all of them there is definite infiltration, particularly on the right side. The outline of the diaphragm tends to be irregular and flattened, and the root shadows to be enlarged in a downward direction. Without going into further detail, the picture is that of asbestosis. But the shadow of the fibrosed zone is in itself characteristic. It is devoid of radiations from the root shadow and presents an amorphous, flocculent appearance, in which small cavities are indicated in some of the cases. In estimating the respiratory handicap we must not forget that the bases extend below the shadow of the dome of the diaphragm.

Lung Puncture.—Another line of investigation, suggested by Dr. Henry, has been carried out—namely, lung puncture. Asbestosis bodies can be extracted from the patients' lungs during life by means of a hollow needle and syringe. I punctured all these four cases, and Professor Stewart has found "bodies" in two of them. We do not recommend it as a routine method of diagnosis. No tubercle bacilli were found in any of them.

Sputum.—Much preferable is the examination of sputum by the antiformin method, which Professor Stewart has applied with striking success, and the only difficulty is to get the sputum. This is often available in winter, and if the patient has a receptacle in readiness the sputum will turn up some time. Three of these cases yielded the "bodies" in sputum, and the fourth had no sputum but was positive on lung puncture.

Conclusions.

The following conclusions have been established:

1. That the inhalation of asbestos dust will "in the long run" produce a state of fibrosis, the distribution being peripheral and mainly basal, the right base becoming most advanced and the upper lobes tending to develop compensatory emphysema as first the diaphragmatic and gradually the entire pleural surfaces become obliterated.

2. That the disease is not as a rule complicated by tuberculosis.

3. That the disease is usually first recognized after more than five years' exposure, although systematic examinations might reveal it earlier.

4. That the condition is usually found first during an attack of influenza or winter cold, when exacerbations of the disease occur.

5. That even in the advanced cases there is marked abatement during the summer months.

6. That the onset of anorexia signalizes to the worker that work is no longer possible.

7. That the patient may then live for several years and continue to bear children, but becomes progressively weaker and more emaciated, more hopeless, sleepless, and exhausted, until an attack of broncho-pneumonia or bronchitis brings death at last.

8. Further, that asbestosis bodies can be found in the sputum, if any, in all advanced cases, as well as in most early cases.

9. That they can be demonstrated by lung puncture in advanced cases; but since no patient is likely to permit more than one puncture to be made a negative finding is inconclusive.

10. That radiography is of great value in diagnosis and in observing progress.

11. That the treatment of these cases, being purely palliative so far, calls for great patience and vigilance over several years, and much relief can be afforded.

12. Finally, that the disclosure of the danger arising from asbestos dust has brought home to the workers the need for observing the measures provided for their protection, and is bound to be salutary, although the mortality statistics will probably be swelled by the wider recognition of this disease.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A METHOD OF EXAMINING THE SPUTUM FOR ASBESTOSIS BODIES.

HALF an ounce of so of sputum is added to an equal quantity of undiluted antiformin. This is gently agitated until the sputum is completely dissolved, after which it is diluted down with two or three ounces of water and allowed to stand in a large test tube for three or four hours. The bulk of the supernatant fluid having then been decanted, the remainder is centrifuged at a moderate speed for ten to fifteen minutes. The whole of the supernatant is now poured off, and the deposit transferred to an albuminized slide by means of a pipette. After thorough drying on a hot plate and final fixation over a bunsen, the film is very gently washed in water, dried, and mounted in Canada balsam. After a little experience the asbestosis bodies are readily picked up with the low power, and their true nature is then confirmed with the 1/6 inch or oil immersion lens. As a rule they are present in very small numbers, perhaps only one or two in a whole film. In the case of some of the older workers, however, numerous bodies, up to one or two per field in certain portions of the film, have been found. It is obviously necessary to cleanse thoroughly all glassware, etc., used in making these examinations, otherwise there is a risk of contamination of subsequent specimens.

The films can be treated with hydrochloric acid and potassium ferrocyanide to demonstrate the Prussian blue reaction given by the bodies.

Pathology Department, School of Medicine, University of Leeds. M. J. STEWART.

FOREIGN BODY IN THE LARYNX.

THE following case illustrates some of the difficulties of diagnosing the presence of a foreign body in the larynx, and the need, whatever the history may be, for making the most complete examination when this condition is suspected.

The patient, a waitress at a country hotel, consulted Dr. Frend of Hurstpierpoint on January 24th, stating that on the previous evening, as she got up from her chair, where she had been engaged in sewing, she felt a sudden pricking in the throat. After repeated questioning she admitted that she was in the habit of holding pins in her mouth, but stoutly denied that she had done so on this occasion. The meal which she had taken two hours previously contained nothing that could be impacted as a foreign body in the throat. Dr. Frend could see no abnormality in the larynx or pharynx, but with great difficulty he persuaded the patient to go to the Sussex Throat Hospital for further examination.

My examination by indirect laryngoscopy yielded negative findings, but as the patient still complained of the pricking sensation I asked Dr. Prowse to make an *x*-ray examination. I confess that I was surprised to see in the radiogram that a pin was lying, horizontally and in an antero-posterior plane, opposite the sixth cervical vertebra—that is, on a level with the entrance to the larynx. The laryngeal mirror had failed to reveal the presence of this pin, although the patient's larynx had presented no difficulty in examination. I decided to examine with the endoscope, and did so the same evening with the patient under general anaesthesia. I used Lynah's oesophageal spatula, and at once discovered a longitudinal tear about one inch in length on the posterior oesophageal wall. This discovery was soon followed by the sight of a pin-point abrasion on the posterior aspect of the right arytenoid. By making the necessary adjustment in the patient's position I brought the larynx into view, and was able to see the pin transfixed through the right arytenoid, with most of it lying free in the middle of the larynx. I grasped the pin with forceps and inserted the tube a little deeper; by this manœuvre I was able to draw the pin forward wholly into the tube and thus eliminate any possibility of damage to the tissues. The patient wrote on February 17th that she had suffered no soreness or hoarseness, and that she had not felt the least discomfort.

The following features of this case are of special interest: (1) The absence of symptoms, even of the wheezing respiration described by Chevalier Jackson. (2) The unusual position of the pin—foreign bodies in the larynx usually lie with the long axis in the sagittal plane. (3) The failure to see the pin by indirect laryngoscopy. One concludes that it must have been tucked under the aryteno-epiglottidean fold and brought into view as a result of

the relaxation following general anaesthesia. (4) The absence of any after-effects. It is possible that the classical symptoms—namely, hoarseness and soreness, with perhaps some dysphagia—are complained of only when the vocal cords have been the site of impaction. As, however, the arytenoid cartilages are attached to the intrinsic muscles of the larynx and partake freely in the movements of respiration, it is difficult to explain why the congestion following the trauma did not give rise to some sensory impressions. (5) The utter unreliability of the history and the need for the most complete examination of the patient.

It is also interesting to note that, owing to the conviction that the larynx contained no foreign body, one countenanced the use of general anaesthesia. It was fortunate that the pin was fixed, and the patient therefore escaped the possibility of further tragedy resulting from its descent still lower in the respiratory tract.

Honorary Assistant Surgeon, Sussex Throat and Ear Hospital.

SUBARACHNOID HAEMORRHAGE PROBABLY DUE TO RHEUMATIC INFECTION.

PROFESSOR ARTHUR J. HALL'S lecture on three cases of spontaneous subarachnoid haemorrhage, reported in the *British Medical Journal* of June 8th (p. 1025), and Dr. M. C. Andrews's note of a probable case of ruptured subarachnoid aneurysm, in the issue of June 15th (p. 1075), encourage me to report the following case.

A single woman, aged 27, with a previous history of rheumatic fever at 18 years of age and subsequent mitral endocarditis, and also of recurring attacks of bronchial asthma, was seen by her doctor (J. Bernstien) on May 6th, when she complained of pain and tenderness in the right iliac fossa. The temperature was 99° F. There was no rigidity, and the symptoms disappeared in twenty-four hours. Two days later she developed a follicular tonsillitis, accompanied by a typical erythema nodosum on the legs. On May 9th the erythema nodosum appeared on the forearms and broncho-pneumonia developed. The patient became very ill and entered on a "typhoid state," with distended abdomen, incontinence of urine and faeces, and a continuous type of temperature. On May 19th she became delirious and suffered from delusions. An examination at this point showed no head retraction, no Kernig's sign, the Widal reaction was negative, and a blood smear showed an increase in the polymorpholeucocytes. On June 1st she improved, and for two days became rational and the temperature became normal. On June 3rd the temperature again became irregular, and two or three rigors were noted daily. On June 8th I saw her with Dr. Bernstien and admitted her to the isolation hospital as a possible case of tuberculous meningitis.

On admission the patient was severely ill. She was in a state of unconsciousness from which she could be roused. Speech was confused and articulation difficult. The pupils were equal and reacted to light. There was no retraction of the head, Kernig's sign was negative, knee-jerks were present, there was no muscular rigidity, and incontinence of urine and faeces was complete. The temperature was 101.4° F., pulse 120 regular, low tension respiration 38.

An examination of the chest showed a few moist sounds over the whole chest and congestion at the bases. The heart was considerably enlarged and a mitral systolic murmur transmitted towards the axilla, together with a presystolic murmur, was heard. A catheter specimen showed the urine to be loaded with albumin. Lumbar puncture was performed on June 10th. The fluid was under considerable pressure and bright red in colour. The report of the pathologist (Public Health Laboratory, Manchester) was as follows: June 20th. "This specimen consisted of about 7 c.cm. of fluid with a heavy admixture of blood. The only possible examinations were bacteriological ones. Blood agar plates inoculated with the specimen produced a growth of *Streptococcus viridans*. Mice inoculated with the fluid and with the organisms obtained in culture remained healthy."

During the first week after admission the patient's state remained pretty much the same. The temperature ranged between 99° and 101° F., with the evening temperature generally higher. The pulse never dropped below 120, and the respirations below 40; catheter specimens showed less albumin.

On June 18th the condition began to improve. There were lucid intervals, and speech, although obscure by reason of feeble articulation, became at these times coherent. On June 19th the patient became completely conscious, but suffered much from depression and fits of weeping; the incontinence ceased and the albuminuria cleared up. The temperature became normal on June 21st, and the mental state improved. On June 24th the patient had an attack of synovitis in both knees, which cleared up on pressing the dose of sodium salicylate.

At the time of writing the patient is convalescent and mentally normal. She is suffering from disturbance of cardiac compensation which will seriously affect the prognosis.

Medical Officer of Health, Preston.

Reviews.

THE DOCTRINE OF OEDEMA.

THE clinical recognition of oedema as a manifestation of disease demands neither long experience nor special skill; of all symptoms it is one of the most obvious and most easily recognized. Yet it has formed the text of many studies and of numerous dissertations; and physiologists and pathologists and clinicians have in turn sought in various ways to explain the manner of its production. Dr. HERMAN ELWYN'S essay, entitled *Edema and its Treatment*,[1] is a recent contribution to this provocative topic, and it is certainly a contribution of much interest. Whether its conclusions will secure general assent remains to be seen, but the thesis is clearly stated, and is supported by arguments well marshalled and of scientific quality; and in the chapter devoted to treatment even the practitioner to whom theoretical debates make little or no appeal will find not a few practical suggestions.

Dr. Elwyn, for reasons duly stated, rejects the doctrine that oedema is caused either by increase in the capillary blood pressure or by reduction in the protein content of the blood plasma. In opposition to this physico-chemical explanation he sets up the view that oedema results from a disturbance of the physiological mechanism whose duty it is, in the interests of tissue welfare, to maintain at an approximately constant level the total water content of the body, and in particular the water content and volume of the blood. Included in this mechanism are, of course, the circulatory apparatus and the organs of elimination, while the muscles, the skin, and the connective tissues act as natural reservoirs from which water is absorbed into the blood as required; and the normal play and balance of the several parts is controlled by a centre in the midbrain. In this fashion the water movement both to and from the blood is so governed that the blood volume remains practically constant. Should, to take a single example, the urinary output for any reason be diminished, the tendency to a consequent increase in the blood volume is checked—through appropriate action in the nervous control—by diminished water movement from the tissues to the blood; and hence, assuming the intake of water to remain normal, water accumulates in the tissues, and when the saturation point is reached it becomes manifest as oedema.

Such is a very rough illustration of the thesis to the defence of which Dr. Elwyn brings a thorough knowledge of the physical, chemical, and physiological questions involved. He presents his case effectively and cultivates with success a happy faculty of summarizing the successive steps in his argument. His book is not for an occasional half-hour, but those who take it seriously will be repaid for their pains.

THE TREATMENT OF FRACTURES.

DR. LORENZ BÖHLER'S book on *The Treatment of Fractures*,[2] which has been translated into English, is a very practical guide. Dr. Böhler has had nineteen years' experience, including the charge of a fracture hospital during the world war, and his teaching is based on observations on more than ten thousand fractures *in vivo* and three hundred post-mortem examinations. That these observations have been well assimilated is immediately obvious to the reader. Dr. Böhler considers that the too frequent unsatisfactory results in the past have been due in part to anatomical misconceptions and in part to lack of organization and proper technique. He therefore describes in detail all the items and materials needed for the treatment of each kind of fracture, together with the help required by the surgeon. In some cases he frankly states that the necessary treatment can be carried out only in a properly equipped hospital with trained assistance. Most surgeons recommend those methods of treatment of

[1] *Edema and its Treatment.* By Herman Elwyn, M.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. (Demy 8vo, pp. viii + 182; 3 figures. 16s. 6d. net.)

[2] *The Treatment of Fractures.* By Lorenz Böhler, M.D. Authorized English translation by M. E. Steinberg, M.S., M.D. Vienna: W. Maudrich. 1929. (Sup. roy. 8vo, pp. x + 185; 231 figures. 21s.)

which they have had the greatest experience, and Dr. Böhler is no exception to this rule. These methods are skeletal traction by means of tongs or pins for reduction, non-padded plaster-of-Paris splints, applied directly to the skin, for retention, and, as aforesaid, early use of the limb in the retentive plaster splint.

Three fundamental rules for the treatment of fractures are set forth. "(1) The peripheral fragment must always be placed [sic] in the direction where the central one points. (2) Every fracture must be reduced by traction and countertraction. (3) After the reduction the fragments must be kept in the right position until firm union takes place." If the English of Dr. STEINBERG's translation is a little awkward, no one is likely to quarrel with the sense of these rules. For the treatment of some fractures Dr. Böhler uses strong arguments in favour of certain positions, which differ from those recommended by most authorities. Thus, for supracondyloid fractures of the humerus he condemns the usually recommended position and prefers one of pronation, because, he says, the pronators are also flexors of the elbow and should be relaxed to enable the fragments to be properly reduced. Shortening must be corrected by weight or screw extension, maintained until the retentive plaster cast has hardened; lateral displacement, if not corrected by extension, must be corrected by lateral pressure. As to immobilization in plaster, he lays stress on the following contention: "If we reduce exactly a broken joint and continuously hold it in a good position until union takes place, and at the same time allow the use of the fractured extremity, we obtain a movable joint, while on the other hand, if we apply massage and passive movements in the first days after the fracture, the joint becomes stiff."

In no cases does Dr. Böhler approve of the use of wires, plates, nails, or screws; and even for fractured patella he will not suture the bones, but pays particular attention to suturing of the torn fascia, tendon, and aponeurosis. He truly says that the patella is no more than a sesamoid bone, and that it is reunion of its tendon which is essential. When that is secured and the fractured bone-faces are cleared and brought together, bony union will follow. Apparently his experience of bone plating and nailing has been unfortunate, for there is no doubt that such methods are useful in suitable cases, and that the rarefying osteitis which is alleged to result from plating is more an accident than a usual sequel. The importance of anatomical restoration of the shape of the parts is insisted upon, especially when a joint is involved, and, to secure this, powerful screw appliances are employed to squeeze together displaced portions of bone, such as the condyles of the femur or the malleoli at the ankle.

With his carefully thought out technique and apparatus and his well-trained assistants Dr. Böhler has no doubt achieved great success in treatment. His book, nevertheless, is not a guide for the general practitioner, because many of his methods can only be successfully applied in well-equipped hospitals. To any hospital surgeon who is constantly treating fractures the book should be stimulating, for it challenges principles of treatment which are widely accepted. It is well illustrated, but the translation into English is not quite as idiomatic as might be desired.

TREATMENT OF HAEMORRHOIDS.

DR. J. F. MONTAGUE's book on the *Modern Treatment of Hemorrhoids*[3] is written primarily for the general practitioner and contains much that is commendable. The distinction between internal and external piles is clearly drawn, and in the chapters on signs, symptoms, and diagnosis the author thoroughly justifies the existence of the book by the stress he lays on the necessity for thorough examination of every case with rectal symptoms. This is a point which cannot be made too often. Treatment is considered under the heads of palliation, operation, injection, radium, and electrical methods; the author describes very well the ligature and cautery methods, and much useful detail is given in regard to preparation and after-treatment. We oppose the author's advocation of operative removal of ulcerated or gangrenous internal piles, which teaching we consider to be dangerous and liable to lead to post-operative ulceration; if an internal pile is septic or gangrenous Nature will generally effect a spontaneous cure if the patient is put to bed, with local application of moist antiseptic dressings. The method of treating bleeding piles by insertion of radon seeds is of interest. We are told that fibrosis and cessation of bleeding occur fairly constantly, but it would appear that, compared with carbolic injections or operation, the method does not promise to be of much practical use; also, it is well known that a troublesome proctitis is liable to follow the insertion of radium into the rectum. If this should happen in the course of treatment of a malignant tumour it would not cause much anxiety, but a proctitis following treatment of a simple vascular pile would be a regrettable complication. As regards injection treatment of piles, Dr. Montague uses a 10 per cent. solution of cresylic acid in glycerin and water, and only employs this method in cases of uncomplicated internal piles; this is the usual and the safe teaching. Precise instructions should have been given in a book of this sort as to where the selected solution should be injected and in what amounts; moreover, the diagrams illustrating his technique should certainly not be copied closely by anyone not acquainted with the method, or trouble would be likely to ensue from too low injection of the solution.

For further details regarding the injection treatment, Dr. MARION PRUITT's recent monograph[4] is available; here we find accurate information regarding suitable specula and average dosage, and, above all, we find insistence on injection of the selected solution well above the mucocutaneous junction. A somewhat startling feature is Dr. Pruitt's treatment of prolapsed piles of the third degree by carbolic injection. Provided that the sphincter is relaxed, the author considers it safe to inject the piles and to leave them prolapsed; the protruded mass takes three to eight days to recede, and the cases have apparently done well. Some selected case reports are given of piles of the various degrees treated by carbolic injection. The nine contraindications to the injection treatment which are set out in chapter 16 should be noted and observed by all who practise this method.

PRINCIPLES OF PATHOLOGY.

"IN offering to the medical world one more treatise on pathology, it would seem necessary, if not to make an apology, at least to give an explanation. We have a number of textbooks on the subject in the English language all of which give the current knowledge accurately and often with much detail." POWER and HALA's book on the *Principles of Pathology*[5] is prefaced with these apt remarks. They hold that most of the textbooks in use have rather the character of works of reference, and have not been written from the instructor's point of view; they contain, therefore, much that should properly be relegated to the encyclopaedias. For example, the authors consider that the natural history of insects, worms, and bacteria is no more a part of pathology than is the study of predatory animals, regarded as a possible cause of injury. They further consider that the study of pathology is greatly hampered by a superabundant, overlapping, and often misleading nomenclature; and, we may add, the Americans are particular sinners in this respect. The authors have kept these points in view in planning their work. A foreword contributed by Charles Norris of New York City states that the book is "individualistic and modern, giving due consideration to physiological and chemical pathology, a striking contrast to many of the German and English

texts, which neglect to emphasize the importance of this aspect of the subject." The last observation appears to us to be singularly wide of the mark, if a clear distinction is recognized between pathology and pathological anatomy. He explains that the book is not addressed specially to expert pathologists, but the latter "are advised that many of the problems of pathology are presented in a new and novel form which must necessarily stimulate further research," and he recommends the book not only to the student and practitioner, but even to the layman. An appendix contains a good account of photographic technique in connexion with the illustration of works on pathological anatomy; one would have expected to find the figures in the body of the work approaching in some degree the standard there laid down.

SPEECH AND HEARING.

IN the University of Capetown there has been established a somewhat new and most laudable practice of giving to every student training as a school teacher systematic discipline, both in correct speech for himself and in the ways of securing it in pupils. A few of the students receive special training with a view to becoming speech experts themselves. In the pursuit of this work there was found a need for a handy book upon the anatomy and general physiology of the organs of speech. This want has been supplied by a little book entitled *A Short Course on the Mechanism of Voice and Speech*[6] written by Professor M. R. DRENNAN, professor of anatomy in the University. Professor Drennan has taken some share in the training of these student teachers, and the book covers all that has been found needful for the course of instruction. There is a simple and straightforward account of the anatomy of the organs involved in voice production, also a short chapter on elementary acoustics, on the anatomy of the ear, and on the nervous mechanism of speech and hearing. The little book is well done, and should prove useful to teachers and students. To each chapter is appended a bibliography of books of reference that may be usefully consulted for further information. The illustrations are numerous, but not altogether satisfactory. The frontispiece, giving half-tone photographic reproductions of the larynx, must be almost meaningless to the layman. Many of the others are diagrams of the blackboard type, which, though they are perfectly satisfactory in the classroom when the living teacher makes them live before the eyes of his hearers, are flat and lacking life when shown in cold printer's ink. The photograph of the internal ossicles of the ear, done from a large model, is clear and emphatic; this might well be taken as the desirable model for the other illustrations, provided always that there are pointers to each part described, and not merely references at the foot of the picture. There is a racy foreword by Professor F. Clarke, now professor of education of McGill University, and formerly dean of the faculty of education at Capetown University. He shows how necessary is training in diction in countries where there is a bilingual practice, otherwise painfully mongrel enunciations develop which are injurious to both languages.

A book of quite a different order comes to us from the Bell Telephone Laboratories, *Speech and Hearing*,[7] by HARVEY FLETCHER, acoustical research director of the laboratories. It is the record of work carried on for some fifteen years. The aim has been to get an accurate physical description and a measure of the mechanical operation of the human ears in such terms that these may be related directly to electrical and acoustical instruments; to test the keenness of the sound-discriminating sense and find what is the smallest distortion which the mind can perceive, and how it reacts to somewhat larger distortions. The direct purpose of these researches has been the increase of exact knowledge as to the requirements of speech in the telephone system, for it is recognized that there must be an evolution towards even greater perfection in those particular elements which are most important to intelligibility. Incidentally the work has been fruitful in other directions. Modern phonographic records are produced with an electrical transmitter which was developed in the early stages of these studies; and radio broadcasting has grown up round this same "microphone." This book is the most comprehensive and detailed piece of work of the kind we have seen, and it will no doubt be welcomed by all interested in these branches of investigation.

[6] *A Short Course on the Mechanism of Voice and Speech.* By M. R. Drennan, M.B., F.R.C.S.E., etc. Capetown: The Mercantile Press. 1929. (Cr. 8vo, pp. 67; 20 figures. 5s. 6d. net.)

[7] *Speech and Hearing.* By Harvey Fletcher, Ph.D. With an introduction by H. D. Arnold, Ph.D. London: Macmillan and Co., Ltd. 1929. (Med. 8vo, pp. xv + 331; 151 figures. 21s. net.)

NOTES ON BOOKS.

Your Eyes and their Care[8] is a little book by Dr. EDGAR S. THOMSON of New York, designed to give guidance to the laity on the care of their own and their children's eyes. The object is laudable, but we are not sure that it has been achieved. There is the usual sketchy anatomical review, then follow some useful hints on reading and the dangers of fatigue. Diseases are grouped under those affecting the developmental period and those of adult years, which is sound practice. But in the former ophthalmia neonatorum gets a bare three pages; we are told that the infection is "caused by the gonococcus of Neisser," and that it "is caused by infection from the mother at birth," but there is no plain statement that will warn the layman of the real origin and seriousness of the disease. Trachoma gets a couple of pages, and vernal catarrh (very rare in this country at any rate) gets a page and a half! We feel, in reading this book, that the author started with a full-sized textbook of ophthalmology before him, and proceeded to cut this down. If he had started with the minds of his readers in view he would have avoided many of his sections and their titles and the sketches of operative procedure, and concentrated upon those forms of instruction which appeal less to the curious than to the genuine seeker after knowledge.

Malaria Problems[9] is a collection of papers published by Dr. F. L. HOFFMAN during the last fourteen years. Dr. Hoffman is consulting statistician to the Prudential Insurance Company, and his papers provide a mass of interesting information regarding the prevalence of malaria throughout the world and the effects produced by antimalarial campaigns. The last paper in the volume, "Recent progress in malaria eradication," written in 1928, is a world survey of the incidence of malaria. The importance of this problem to the British Empire is indicated by the fact that out of thirty countries mentioned twenty are within the Empire. Unfortunately it is only in a few cases that the author is able to report any marked reduction in the incidence of malaria. He is of the general opinion that quinine prophylaxis is an inefficient method of combating this disease, and that the only effectual method is systematic drainage. The volume gives a mass of statistical information, which will be found very useful by those interested in the malaria problem.

A series of memoirs is being published for the Indian Research Fund Association as a supplement to the *Indian Journal of Medical Research*. The thirteenth of these research memoirs deals with *Puzzles and Fallacies in the Examination of Stained Films in the Tropics*,[10] and the joint authors are Lieut.-Colonel R. KNOWLES, I.M.S., professor of protozoology, Lieut.-Colonel HUGH W. ACTON, I.M.S., professor of pathology and bacteriology, and Assistant-Surgeon B. M. DAS GUPTA, assistant professor of protozoology, all of the Calcutta School of Tropical Medicine and Hygiene. This memoir is a particularly valuable exposure of the common errors which may be made in haematological and similar film investigations in tropical climates; it is well illustrated with coloured plates, and can be cordially commended to those who wish to make their technique as perfect as possible.

In *L'Oléothorax*[11] Dr. JACQUELINE FONTAINE has condensed much information about recent work on the intrapleural injection of oil as an alternative to artificial pneumothorax. She has had the advantage of working at sanatoriums where this new therapeutic method was extensively studied and used. The various oils appropriate for different cases and the technique to be adopted are carefully described, as well as mistakes to be avoided and complications that may arise. The type of case for which it is unsuitable is also indicated. Results of about 100 cases, and some skiagrams and diagrams, show what may be expected from oleothorax when it is applied in suitable conditions.

THERAPEUTIC EFFECTS OF ULTRA-VIOLET IRRADIATION.

AN EXPERIMENTAL STUDY.

THREE interesting documents appear together in the recently published report[1] of Dr. Dora Colebrook's investigations of some of the physiological and therapeutic effects attributed to ultra-violet light. First, there is a preface by the Medical Research Council presenting a carefully balanced and just estimate of what appears to be established about the therapeutic uses of ultra-violet light irradiation and what requires further investigation. Secondly, there is an account by Dr. Colebrook of her experimental study of the influence of ultra-violet radiation on the health and growth of school children; and thirdly, a summary, also by Dr. Colebrook, of her findings, with details of all the cases she studied, in an investigation of the effect of ultra-violet light on the healing of varicose ulcers. Both investigations derive scientific value from the fact that they involved the use of exact controls. Thus, a group of children as nearly as possible equivalent to the group receiving radiation from the naked arc lamp was treated simultaneously, and without knowledge of the difference, by exposure to the same arc deprived of its ultra-violet component by a glass screen. A further equivalent group was left without light treatment at all. In the second investigation the changes occurring in irradiated ulcers were compared with those in similar ulcers treated with Unna's paste dressing.

No one reading the reports can fail to be impressed by the great care that was taken to eliminate possible sources of error, to establish sound objective criteria whereby the value of the treatment might be accurately judged, and to sift and evaluate the evidence that finally presented itself. The results of both investigations have already been communicated (Annual Report of the Medical Research Council, 1927–1928), and, as is now well known, they were purely negative. In its prefatory remarks, however, the Council is careful to point out that, like all scientific evidence, Dr. Colebrook's results supply answers only to the precise questions which she chose to put.

> "The results of the Willesden experiment simply mean that the kind of light which Dr. Colebrook used, applied for the periods and at the intervals chosen, to children whose health is good enough for attendance at school, during the months when sunlight and especially its ultra-violet component are deficient, has no measurable effect on their health. It would be legitimate for anybody to criticize her report on the grounds that she used the wrong kinds of rays, applied them too long or too briefly, at intervals too long or too short; but only provided that he can produce valid evidence that some kind of radiation, applied under conditions attainable in the wholesale treatment of school children, has a beneficial effect demonstrable under conditions as critically controlled as those of Dr. Colebrook's experiment."

While, however, it may be admitted that scientifically it would be illegitimate to generalize the application of Dr. Colebrook's negative results, there can be little doubt that if other workers repeating her investigations obtain similar findings, then a case very difficult to refute would be established against the value of administering ultra-violet radiation to children under the conditions of her experiment. But scepticism, no less than any other attitude valuable in scientific investigation, has its limits. As long as there is a reasonable probability that a remedy may be causally related to benefit that has been known to follow its application, then the medical practitioner is justified in continuing to use it.

IRRADIATION OF SCHOOL CHILDREN.

The children studied were those attending a Willesden Council infant school. The average number on the register was 250, the ages ranged from 5 to 7 years, and the number of boys exceeded that of girls by about 4 per cent. The area from which the children were drawn was considered a suitable one in that the conditions were not bad enough to counteract any favourable effect resulting from the irradiation, while they fell short of a standard for which no added hygienic measures were desirable. The children were divided into three groups, two of which were irradiated, the one by a naked arc lamp, the other by a similar lamp from which all but the very longest ultra-violet rays were excluded by a window-glass screen: the third group received no irradiation at all. Records were kept of heights and weights, incidence and duration of colds and allied conditions, incidence of infectious fevers, occurrence of chilblains, progress in school work, and causes of absence. The inquiry lasted from the end of August, 1927, to the end of March, 1928, and thus included two school terms. During the period of inquiry the children were kept under close observation by the investigator (Dr. Dora Colebrook) and by a whole-time nurse, whose business was to carry out the treatment under Dr. Colebrook's supervision, to visit each classroom daily, to check the records of colds kept by the teachers, to investigate complaints of sickness, and to visit the homes in all cases of absence. The purpose of the inquiry was described to the school staff, and every precaution was taken to avoid the influence of contributory factors on the results. No attempt was made to induce the parents in any way to modify the mode of life or habits of the children.

Dr. Colebrook describes in considerable detail the room which was set apart for the treatment, the arrangements for regulating its ventilation and temperature, the lamps employed and their intensity, the method of screening, and the technique used in the irradiation. In estimating the dosage the standard aimed at was to give exposures of such intensity that an erythema reaction would be just avoided on the skin of a child of average sensibility, and, by slowly increasing the intensity of irradiation, to maintain that level throughout. Dosage was regulated in this way, not only with a view to keeping pace with such tolerance as is developed to light of even moderate intensity, but to obtain a comparison between the relative merits of smaller and larger doses.

In allotting the children to the three groups more were deliberately placed in the light groups than in the control group, because it was obvious that for one reason or another children would fall out of them before the end of the investigation, whereas so long as a control child remained in the school it remained a member of the group. Furthermore, it was felt that the treated groups were better controls for each other than the control group was for either: they shared certain general experiences which the untreated missed; they were withdrawn from their lessons for similar periods, exposed to the same changes of temperature, and some of them received extra baths at home in preparation for the undressing at school.

At the time of the first treatment there were 80 children in the unscreened lamp group, 90 in the screened lamp group, and 76 in the group of controls. By the end of the inquiry 101, 94, and 92 children had passed through each of these groups respectively. Throughout the period of the inquiry children entered and left the groups. The changes in personnel were slight, but in calculating the final results of the investigation Dr. Colebrook took every precaution to make the fullest allowance for the variations that occurred. It may be added that from the data presented in the report it is reasonable to assume that the children in the control group were a fair sample of the whole. For various reasons, mostly connected with deterioration of health, eighteen children were withdrawn from the unscreened and nineteen from the screened lamp group in the course of the investigation. In view of the ultimate results it is noteworthy that, while no child could leave the control group for health reasons, the average standard of health of the light groups tended to be raised by these withdrawals.

RESULTS OF THE INVESTIGATION.

Increase in Height.

The average height in each group was measured at the beginning and at the end of the period of investigation, and a table summarizing the results for each of the three groups is given in the report. The variability within each group is indicated in the table by the standard deviation and coefficient of variation; furthermore, the two light groups were classified into two subgroups in order to decide whether any distinction could be made between those receiving the full course of

[1] Medical Research Council. Special Report Series, No. 131. *Irradiation and Health: Two Experimental Studies.* By Dora Colebrook, M.M. Stationery Office. 1929. Price 1s. 6d.

treatment and those receiving the lesser amount. It is clear from the figures that there was no significant difference either between the subgroups in each group or between the main groups—in other words, no evidence could be derived from Dr. Colebrook's investigation that irradiation under the conditions of her experiments had any effect on the rate of stature increase in children.

Increase in Weight.

Weights were measured, correct to 0.1 kilogram, seven times during the whole period. When a child missed a weighing day *it was weighed on the first possible occasion after it.* The figures for the whole period show that there was no advantage to the light groups, there being only very small and insignificant differences favourable to the control children. The rate of growth of the light groups, however, contrasted in an interesting way with that of the group of controls. Whereas the general character of the control weight curve does not suggest any seasonal influence in the period of the investigation, the weight curves of the light group show for the unscreened groups periods of maximum increase from September to October and January to February, and for the screened group a similar increase from October to November and January to February. These two periods represent the time when the stimulating effect from the treatment might be most likely to show itself, and, if such an effect could reasonably be inferred from the curves in question, it would appear that the same influence was felt in both groups. In the weeks following these periods of maximum increase both groups made a relatively smaller gain, so that on the whole the balance was adjusted.

Liability to Colds.

The liability to colds in the three groups was compared: (*a*) by calculating the number of colds in each group per 100 child-weeks of exposure to risk; (*b*) by expressing the total number of days of duration of all colds as a *percentage of the* number of child-days of exposure. The exposure was estimated as the sum of the days of attendance at school and the days (school days) spent at home with a cold.

The figures for the light groups were based on the convention that a child belonged to them for six weeks after its last exposure, and in calculating the number of colds a cold was considered a new one on a certain day if there had been no record of it for six previous calendar days. The duration of colds for the whole period was estimated in two ways: (1) as "duration of cold-time," which was the ratio of the sum of the actual days of duration of all colds to the actual days of exposure, expressed as a percentage; and (2) "duration per cold," by which was meant the average duration of each cold with the proportion of school days in each spent at home and in school. Various sources of possible inaccuracy are mentioned in the report, and precautions are described whereby in the final calculations errors that might have arisen from them were avoided. From a study of the various charts and tables it is clear that neither in the figures for the whole period, nor in the monthly records, did the condition of the children of the unscreened group show any superiority over that of the screened or the control group. What little advantage there was in respect of number and duration of colds appeared in the two latter groups.

The figures, it must be emphasized, do not support a claim that the effect of the unscreened lamp was actually harmful. In order to investigate such a possibility the figures for each child for every week would have to be analysed separately and the probable error calculated. In view of the actual smallness of the differences observed and of the amount of unavoidable error, even when great care was used in the method of recording, such a procedure did not seem to be warranted. The monthly records show that a disparity between the groups —with the balance in favour of the control and screened lamp groups—tended to be greater in the early months of the investigation, when the intensity of irradiation was relatively low, than in the later months, when it was relatively high. Over-dosage, therefore, could not be held responsible for the failure of the ultra-violet irradiation to protect. On the other hand, the fact that by the time the investigation was ended a large proportion of the children were pigmented suggests that if irradiation is actually capable of increasing the resistance to colds then the dose was sufficient to elicit a positive result.

Infectious Fevers.

There was no evidence of protection against infectious fevers among the children of either lamp group. The figures of the attack rate were higher among the children of the unscreened group for both whooping-cough and measles; they were lowest for measles in the control group, and for whooping-cough in the screened group. The differences were too small to be significant.

Incidence of other Conditions.

During or immediately after the treatment period the incidence of various morbid conditions on each of the groups was as follows: in the unscreened lamp group, diphtheria (1 case), chicken-pox (2), tonsillitis (4), acute cervical adenitis (1); in the *screened lamp group*, scarlet fever (1), chicken-pox (4), tonsillitis (2), pneumonia (2), bronchitis (2), otitis media (3); in the control group, scarlet fever (1), chicken-pox (1), otitis media (3). In the control group a boy with a strong family history of tuberculosis was reported to have been certified as having phthisis. Mild cases of impetigo occurred in all groups; herpes labialis also was roughly equally distributed and of very common occurrence. Chilblains were observed in twenty-nine children only, their group distribution being in the unscreened group fourteen, in the screened group ten, and in the control group five. There was no appreciable difference between the three groups in the progress of their members in school work.

Subjective Impressions.

The subjective impressions of the medical officer were indefinite, her general impression being that where improvement in health occurred it appeared to be an individual rather than a group manifestation. Among the parents the balance of opinion was in favour of the unscreened group, and among the teachers in favour of *both lamp groups, the screened group* taking first place.

IRRADIATION OF VARICOSE ULCERS.

In many published reports of cases in which successful healing of varicose ulcers has been attributed to irradiation, reference has also been made to the importance of various forms of associated treatment—for example, adequate support to the circulation, or the simultaneous use of some dressing. With a view to ascertaining the exact part played by irradiation the present inquiry concerned itself with a comparison between ulcers treated with light, and covered with simple bandages, and a similar number treated with Unna's paste. The number of ulcers actually treated was eighty-four, but of these fourteen, which for one reason or another afforded no clear evidence of the extent to which the treatment contributed to their healing, were excluded from the analysis of results. Of the *remainder*, thirty-one ulcers were irradiated, twenty-five were treated with the paste dressings, and fourteen were treated with the dressings after an unsuccessful trial of irradiation. There was no selection of the cases.

Dr. Colebrook describes in some detail the technique of each of the treatments adopted and the method used for recording the size of the ulcers. The irradiated series received all degrees of dosage, but in every case the application was local. The milder doses were given twice or thrice weekly, the stronger doses at somewhat longer intervals. When progress was unsatisfactory treatment was suspended while the patient was kept under observation: where moderate doses failed the intensity of irradiation was increased. It is noteworthy, however, that the method approved by many actinotherapists of applying irradiation to the patient rather than to the ulcer was not adopted. From the figures in the various tables it seems clear that in the treatment of *ambulant patients* Unna's method gave decidedly better results than irradiation, no fewer than 76 per cent. having been cured by the former and none by the latter. In the treatment of bed cases the difference is far less marked, what evidence there is suggesting that rest, rather than the treatment, is the important factor contributing to healing. The suggestion that light itself played an unimportant part was supported by the following observations made in the irradiated series: (*a*) the behaviour of irradiated and non-irradiated areas or ulcers was similar; (*b*) in many cases progress was not maintained, or relapses occurred, and in these a continuation or a further course of similar treatment to the relapsed area was ineffective. It is noteworthy also that relief of symptoms, which was a marked feature of the cases treated by Unna's paste, was not obtained during light treatment.

British Medical Journal.

SATURDAY, SEPTEMBER 28TH, 1929.

DIVERTICULITIS OF THE COLON.

MANY of the advances in medical knowledge have had much the same history, the details varying indeed, but the main outlines being strikingly similar. Thus, a discovery, perhaps about a disease or a method of treatment, is made and recorded, but its importance may not be appreciated, either because the discoverer does not recognize its full implications, or his fellows are unwilling or unable to accept the new idea. There follows then a more or less prolonged period during which isolated cases or groups of cases are cited and published. The cases of the earlier part of this period tend to present the interesting features, those of the later part the unusual aspects of the subject; and among this casuistic literature certain papers stand out as throwing light—albeit somewhat distorted—upon the matter as a whole. In the next stage, by a happy generalization or by a careful compilation of observations, a sure foundation is found in the facts of physiology or pathology. When this has once been accepted the building of the superstructure is rapid; corners are rounded off, old and new observations are found to fit into appropriate places, and the conception is available for assimilation into medical knowledge and for use in medical practice. Some such story is that of the condition known, for want of a better term, as diverticulitis of the colon.

The fact of diverticula formation in the colon, though it has been known for a century or more, has not yet entered fully into the clinical consciousness of medical practitioners or been given that place in the textbooks which its frequency and importance merit. Already before the middle of the last century Rokitansky had described the characteristics of false or acquired diverticula of the intestinal tract, as distinct from the true or congenital diverticula such as Meckel's diverticulum, and his work was made available for English readers in the Sydenham Society's translation of 1849. According to Rokitansky the false or acquired diverticulum occurs as a lateral dilatation of the intestine, and is a hernia of the intestinal mucous membrane, resulting from the separation of the fibres of the muscular coat. False diverticula thus consist solely of mucous membrane and peritoneum. They occur at the duodenum and in the entire course of the small and large intestines. They are found in considerable numbers, more especially in the colon, as nipple-shaped appendages, which occasionally are grouped in bunches. Those in the colon retain faeces, which dry up and form stony concretions.

Diverticula are commonest in the colon, and during the next fifty or sixty years many cases of disease due to the presence or complications of diverticula or sacculi of the colon were reported. The sigmoid colon being most often affected, groups of cases were collected presenting symptoms of left-sided peritoneal or pelvic inflammation, or of a chronic stenosing hypertrophic inflammation mimicking cancer (Moynihan). Telling and Gruner in 1917 published a paper which fully set out the literature and knowledge of the subject up to that date. They [illegible] essential underlying pathological formation—in this large group of cases, and offered a sound and practical classification based on the pathological changes that may occur. The advances in x-ray knowledge and technique led to the discovery of diverticula at a time before inflammation had occurred—a pre-diverticulitis stage which Spriggs in 1920 proposed should be termed diverticulosis. Later work shows that a revision of our views on the frequency with which diverticula of the colon occur is necessary, since x-ray examinations have demonstrated them in 5 to 10 per cent. of persons over the age of 40. They have been found in 5 to 7 per cent. of necropsies when careful search has been made. They were overlooked formerly, even by experienced morbid anatomists, probably because they are small in size and usually embedded in fat or buried as a result of inflammatory changes taking place around them. These false diverticula of the colon can no longer be regarded as purely congenital. Occurring as they do so often in persons who are more than 40 years old, they can be observed with the help of x rays to have developed in portions of bowel previously healthy. In the colon they are found most frequently near the convexity of the gut; they are usually multiple, and occur in two rows. Their origin may be due to degenerative changes in the musculature of the bowel, in which the vessel holes and attachments of the fatty appendices epiploicae are already sites of lowered resistance. A more satisfactory explanation, however, is that slight inflammatory changes cause relaxation of the bowel wall, so that internal pressure produces small herniae of the mucous membrane through the weakened muscle.

The fact, then, of diverticula formation being accepted, the phenomena associated with it may be deduced from a consideration of the pathological possibilities. Infection may occur, of either acute or chronic nature. In the former case perforation and peritonitis may ensue, or a local abscess may develop and be complicated at times by fistula formation with neighbouring viscera. In chronic inflammation, or peridiverticulitis, thickening may give rise to stenosis or to the formation of a mass which simulates new growth. True cancer, moreover, may be associated with diverticulitis, being here, as elsewhere, probably related to the effects of chronic irritation. Consideration must also be given to the stage before inflammation occurs, when, though the condition is latent and symptoms are mostly absent, there is a potential danger. Any treatment of the matter should therefore embrace the medical or prophylactic aspect, as well as the surgical management of the complications that may arise.

The interest of the profession in this subject was shown by the large attendance of members at the meeting of the Surgical Section of the Annual Meeting of the British Medical Association which was recently held in Manchester. A report of the meeting was published in the *Journal* of August 3rd at page 189, and in the present issue the opening papers by Dr. E. I. Spriggs and Dr. William J. Mayo are printed in full. Dr. Spriggs (p. 569) dealt primarily with his own experiences of the medical treatment of the condition, and he emphasized the importance of the x-ray examination in the diagnosis both of diverticula and of the stage which the disease has reached. His method of treatment, which he described in full, consists of dieting, general hygiene, the administration of liquid paraffin, and the performance of gentle irrigation of the bowel. By this means a healthier condition of the colon is brought about, and complications may be prevented; the early stages of diverticulitis may be made to subside. Even obstructive symptoms, if they are due to the presence of an inflamed and oedematous mucosa, will yield to conservative treatment. The need for surgical intervention will thus

arise only in neglected cases of diverticulitis or in those in which inflammatory complications have caused fibrous stenosis or have involved the peritoneum or adjacent viscera. In addition to the stage of formed diverticula, Spriggs recognizes a pre-diverticular stage, discernible by x-ray examination, and has found histological evidence of pathological change in the bowel wall antecedent to the formation of the pouches. In this early stage the disease can be arrested by suitable medical treatment. Dr. Mayo's contribution (p. 574) naturally dealt more with the surgical aspects of diverticulitis, a stage reached by some 10 to 12 per cent. of cases of diverticulosis. He offered a classification according to the spread of the inflammatory reaction in and around the diverticulitic area, and described the symptoms peculiar to each group, with the appropriate treatment. He made special reference to cancer of the descending colon as a possible result of diverticulitis, and to the difficulties in the differential diagnosis of the two conditions. Carcinoma of the sigmoid was, in his experience, twice as common as diverticulitis.

The succeeding discussion revealed a considerable divergence of opinion as to the indications for surgical intervention in cases of diverticulitis. The majority of speakers reserved surgery for the treatment of its complications and emergencies. Mr. Lockhart-Mummery, however, urged that earlier operation would give better results in a disease which, once established, tends to be progressive and to lead to disaster. The discussion was conducted in a spirit of friendliness which is a good augury for the successful solution of the problems of treatment in this difficult and variable condition.

THE DIAGNOSIS OF ARSENIC POISONING.

THE poisonous properties of arsenic were known long before the Christian era, and its effects were described by Dioscorides as early as A.D. 40–90. It became the favourite drug of the professional poisoners who flourished in the fifteenth and sixteenth centuries. Tofana, for example, is stated to have poisoned by its means at least 600 people, including two Popes—Pius III and Clement XIV. She is supposed to have prepared her "Acquetta di Napoli" by rubbing arsenic into hog flesh and collecting the juice which dropped from the meat. A substance without colour, taste, or smell, which is unerring in its action, and which causes symptoms resembling those of natural disease, possesses most of the requisites of the ideal poison. If, in addition, it is difficult to detect, its appeal to the criminal must be almost irresistible. In earlier years arsenic had this last attribute also, but by the discovery of the Marsh test in 1836 it became of all poisons the most easily recognizable in minute quantities. In spite, however, of this test arsenic would still appear to rank as the most popular agent for homicidal purposes, and in practically all the *causes célèbres* of recent years it has been the poison used. Such cases have excited the public interest—for example, the Madeleine Smith, Maybrick, Seddon, Greenwood, Armstrong, Pace, and the recent Croydon cases—and have given arsenic priority as the most commonly used poison. It would, however, be rash to assume without further inquiry that this ill repute of arsenic is founded in fact, and it may well be asked whether arsenic may not have acquired its unenviable notoriety merely because of the ease with which it may be detected in small traces.

In the investigation of cases of death from arsenic poisoning the question of the time when the poison was given is usually of paramount importance. If the period which has elapsed between the ingestion of the drug and the death of the victim can be ascertained with any degree of certainty it may become one of the deciding factors in the elucidation of a case in which its administration for criminal purposes is suspected. In giving an opinion about this period medical men are guided to a considerable extent by the relative distribution of the poison along the alimentary canal, and by the relation between this amount and the quantity absorbed into such solid viscera as the liver and kidneys. There are, however, many variables to be considered in this connexion: for example, particles of arsenic given in powdered form may long remain closely adherent to the mucous membrane of the stomach, and the discovery of a quantity of arsenic in this organ and of comparatively little in the lower bowel may lead to an erroneous assumption about the time of ingestion. The function of the keratin tissues in the absorption of arsenic does not appear to have received the attention which it deserves, although on many occasions the metal has been detected in the hair, nails, and epidermis of persons poisoned by the drug. Whether or not there is a selective absorption of arsenic by the keratin tissues there is no doubt that the poison is to be found in the hair after even a single dose, and that it remains in this and other such tissues for a considerable time. If we can assume that the metal is absorbed by the growing cells of the hair papillae, and, being passed into the hair as it grows, remains in these avascular structures, there arises the possibility of acquiring more definite evidence about the time when the poison was given.

An investigation into the arsenic content of hair and its position in the hair fibre should thus be of value, and we welcome in this connexion an interesting contribution by Althausen and Gunther in the *Journal of the American Medical Association* of June 15th. These investigators report that the hair is one of the main channels for the elimination of arsenic from the body, and that in subacute and chronic cases the arsenic content of hair per unit of weight surpasses that of all other tissues. They also believe that hair retains the metal for longer periods than any other structure of the body. During their research they found that many hair restorers and soaps contained it in varying quantities—an observation which conveys a warning to those examining hair for this metal. It is mentioned also that arsenic cannot be demonstrated in the hair until five days after its administration. Though we do not necessarily agree with the whole of the conclusions of the two American investigators, their paper should prove an incentive to further research into this important subject.

INTERNATIONAL HEALTH SERVICES.

THE League of Nations proposes to spend on its health services next year the sum of 1,750,000 Swiss francs. Such is the estimate which was laid before the Budget Committee of the Assembly at Geneva last week. It is a small sum in comparison with what the work achieved by the Health Organization might be expected to cost, and, even so, only a little more than half of it represents the League's contribution, the remainder being a grant from the International Health Division of the Rockefeller Foundation. The League bears the expense of the salaries of its own health section, consisting of the medical director (who receives £2,120 a year) and a staff of twenty-eight persons. The Rockefeller Foundation makes itself responsible for a large part of the technical and research work of the organization, which involves the employment of a so-called

temporary staff, including the chief epidemiological officer and the official in charge of special investigations (each of whom receives annually about £1,500), together with fourteen others. A part of the grant of the Rockefeller Foundation is also expended on the liaison system between the various national health services, and on the maintenance of the Singapore intelligence bureau. This Eastern bureau, to which China, Japan, and other Eastern countries make contributions, is doing an increasingly useful work. The ports in weekly telegraphic communication with the bureau include all the important ones in oriental seas, except some in China, and progress is being made even in respect to these. During the past year the number of health administrations receiving the weekly bulletin from Singapore increased to twenty-nine. A large number of wireless stations now broadcast the weekly message in a special code for the benefit of shipping, and a summary of the message in "clear." Information concerning 160 ships having on board patients suffering from infectious diseases was received and transmitted last year. Between the regional bureau at Alexandria and the "base" at Singapore news is passed as to the movement of pilgrims and the occurrence of disease among them, as well as the precautionary measures taken before their departure, so that the bureau is in a position to give prompt advice to the health administrations concerned. Other activities directed from Singapore include the co-ordination of medical research work carried out in the Far East, with reference particularly to the study of oral vaccination against cholera and plague; the bureau also acts as an agent of liaison between the laboratories and institutes of the Orient. One of the features of the present Assembly at Geneva is the big effort made by the British delegation to place the staff of the secretariat of the League of Nations and the International Labour Office in a similar position to that of the British civil service. This may seem to be a domestic matter in comparison with the wide concerns of the League, but if the proposals are accepted they may bear very important fruit in the future. The proposals, which were expounded by Dr. Hugh Dalton, M.P., aim at giving the members of the staff as far as possible permanent employment on contracts of long duration, opening all the higher posts to promotion from the ranks (instead of, as at present, bringing in middle-aged persons from the diplomatic or technical services of various countries), establishing a system of recruitment whereby posts may in the long run be distributed equitably among the nationalities, and, finally, providing for adequate pensions. Dr. Dalton hopes that the new arrangements may succeed in attracting to the service of the League of Nations some of the very best young men and women from all the member States, for the service to be rendered to the cause of constructive peace should appeal to the ideals of the ablest of the younger generation. It should be added that in this field, as in others, the strong British delegation at this Assembly is setting the pace, and is recovering for Great Britain that initiative in League affairs which in recent years has seemed to be on the wane.

THE LEAGUE OF NATIONS AND DANGEROUS DRUGS.

Among the less prominent problems engaging the attention of the tenth Assembly of the League of Nations, recently in session at Geneva, was that of the traffic in opium and other dangerous drugs. The report of the work of the twelfth meeting of the Advisory Committee, held earlier in the year, came under review by one or more of the Assembly's Commissions, together with a memorandum thereon by the representative of Canada as rapporteur. Some reference to the recent work of the Advisory Committee on Opium appeared in the *Journal* on February 2nd (p. 213) and May 18th (p. 918). The Council of the League has had under consideration the organization of the Permanent Central Opium Board, but the precise relationship between this new body set up under the Geneva Convention of 1925 and the Advisory Committee, which has been at work for some years, does not appear to have been determined. The third meeting of the Board will be held next month, and presumably it will then be in a position to take over some of the work hitherto performed by the Advisory Committee. The rapporteur, in commenting on the report of the Advisory Committee, laments with them that half the number of States members of the League have failed to ratify the Geneva Convention of four years ago. Uncertainty prevails as to the extent and nature of the control of imports and exports of the scheduled drugs. Attention is called to the fact that two new drugs—namely, methylecgonine and benzoylecgonine—are subject to the requirements of the Convention. There is also remissness on the part of many States, including even some which are members of the Council, in furnishing reports in regard to production and distribution of opium, although these have been repeatedly asked for. Indeed, Persia and Turkey, two of the largest opium-producing countries, have vouchsafed no reports at all. Moreover, there was an unexplained discrepancy between the export statistics given by the Persian authorities and the amounts recorded by other Governments of imports derived from Persia. Attention is again drawn to the notorious case of illicit transactions by a Dutch firm, referred to in the *Journal* of February 2nd (p. 213). The names of this and three other firms concerned in the contraband commerce are published, and the case is stated to be "the most important and the most detailed one of the kind with which the Committee has had to deal, regarding the ways and manner in which the drugs are supplied to the international illicit traffic." The Committee has asked to be allowed to obtain facsimiles of telegrams sent in connexion with smuggling transactions, but the international guaranteed secrecy of telegrams may preclude the necessary sanction. The International Criminal Police Commission has applied for membership of the Advisory Committee, but, while it is held that the constitution of the Committee does not permit such membership, a representative will be invited to attend when questions of crime and police are under discussion.

THE NINTH INTERNATIONAL CONGRESS OF PSYCHOLOGY.

THIS highly successful congress was held at Yale University, New Haven, Connecticut, from September 1st to 7th, under the presidency of Dr. J. M. Cattell of New York. It was attended by some eleven hundred psychologists, including 122 foreign guests, who were entertained by the University free of charge, and lodged in the Harkness Memorial quadrangle, a modern Gothic building which is justly regarded as one of the triumphs of American architecture. In such a gathering it was only natural that medical subjects should occupy a comparatively small place, but throughout the congress there was plenty to interest the physician and psychiatrist. Perhaps the outstanding contribution was that of Dr. Lashley of Chicago, who, after the banquet of the congress on the evening of September 4th, delivered the presidential address of the American Psychological Association on "The basic neural mechanisms in behaviour." Dr. Lashley's work on the learning of rats, both in their natural state and after they have been subjected to various experimental lesions of the central nervous system, has a deservedly great reputation, and in this address he abandoned his previously somewhat rigid behaviouristic standpoint and demonstrated the capacity of the cortex to act as a whole, and the way in which the nervous system, of the rat at any rate, is capable of vicarious function. He held that any rigid explanation of the physiological correlation of behaviour must be wrong, and that although his own theory must be vague it was

a choice between ambiguity and error. From the medical point of view the other striking address was that of Professor Pavlov, whose lecture was delivered by him in Russian and translated *pari passu* by Dr. Anrep. He described the interaction of the cortical conditioned and subcortical unconditioned reflexes, pointing out that the latter can only be displayed as and when the cortex exhibits the power of minute response to stimuli; on the other hand, the unconditioned reflexes determine and modify the power of the cortex to respond at all. He stressed the fact that a few repetitions of a stimulus will cause inhibition of a cortical conditioned response; while in ordinary circumstances there is no limit to the number of responses of the unconditioned reflex which are possible in the decorticated animal, yet in the normal animal a deep inhibition of the cortex will affect the responses of the unconditioned subcortical reflexes. Further, the state of the subcortical unconditioned reflexes modifies the power of the cortex to respond. Pavlov cited as an example a dog which had grown so old and lethargic, and showed evidence of such rapid and extensive inhibition, that it had ceased to be a useful subject for the experimental study of conditioned reflexes. By means of a Voronoff operation, however, the endocrine balance, a function of subcortical activity, was modified, and for three months the reflexes were restored. A second Voronoff operation once more readjusted the endocrine balance, but the effect finally disappeared after a further period of three months. The official Russian film of Pavlov's work entitled "The mechanism of the brain"—a very clear popular demonstration of the experiments and conclusions of the Leningrad institution—was shown on the afternoon of September 5th. Papers of medical interest were presented in the Section of Abnormal and Clinical Psychology, under the chairmanship of Dr. Jastrow of New York. Dr. Bowman of Utrecht gave a valuable paper on the involution psychoses, while Dr. Grunbaum of Amsterdam showed a cinematograph film illustrating his paper on the apraxics. Both in this section and in others a few of the papers dealt with psycho-pathology and analytic methods, but their number was conspicuously less than has usually been the case at such gatherings in the past. Problems of child guidance, juvenile delinquency, and conduct disorders received a considerable amount of attention, and the products of the great volume of statistical research which has been undertaken all over America in this field were presented. These valuable data concerned the school medical service, adult and children's courts, and general mental hygiene, and were far more copious than any which have been accumulated in this country. It is evident, however, to those who are interested in the development of such work in Great Britain that the problems which have to be faced in the two countries are in many respects fundamentally different, and that in consequence neither the methods nor the conclusions of the American workers can be adopted here without considerable modification. At one of the sessions, for example, it was suggested that in all psychiatric clinics a psychologist—that is, a person who carries out various mental tests—should have equal responsibility with the physician in the diagnosis and treatment of the patients. This illustrated the tendency in American psychology, and perhaps in medicine generally, to overestimate the importance of tests, both physical and mental. These tests are chiefly carried out by women who, having obtained a university degree, expect and obtain employment in the various elaborately and expensively equipped laboratories. The tests are of unequal value, and, while many are very useful adjuvants, there seems a danger that those employing them may come to regard the patient more as an experimental animal than as a human being. It is to be hoped that, in this country at any rate, clinical acumen and clinical judgement will continue to occupy, not only a dominant, but a predominant, position in what our American colleagues would call the patient-doctor situation. Some interesting papers were presented on the effects of various drugs on the cortical activities of animals and on the behaviour of drug addicts, both in America and in the Orient, while both psycho-neurotic and psychotic reactions were considered in the section on maladjustments. Other papers of interest dealt with experiments in hypnosis and the significance of various mental symptoms. Even with such a full programme it was possible to visit the medical school and learn of the admirably equipped and extremely efficient health service which is organized for the undergraduates of the University. It is significant to note that under the auspices of the Commonwealth Fund a full service in mental hygiene is supported, so that there seems no reason why, at least at Yale, American youth should not maintain *mens sana in corpore sano*.

RAISED BLOOD COUNTS.

AN extraordinary wealth of knowledge, condensed and clearly presented, is contained in a small monograph entitled *Polycythaemia, Erythrocytosis and Erythraemia (Vaquez-Osler Syndrome)*,[1] by Dr. F. Parkes Weber and his colleague at the German Hospital, Dr. O. B. Bode. Like all Dr. Parkes Weber's writings, this work is admirably documented—six out of its thirty-four pages are occupied by references to literature—and thought-provoking. The authors describe the activity of the bone marrow in erythraemia as analogous to that in chronic myeloid leukaemia, especially in that rare form where the leukaemic white cells are of a more mature kind, more like polymorphonuclear neutrophil and eosinophil cells, than most of those in ordinary myeloid leukaemia. They also present an interesting summary of erythro-leukaemia, a condition sometimes called Blumenthal's disease, a combination of erythraemia and leukaemia, in which the leukaemic blood picture may supervene on erythraemia or vice versa, and they draw attention to cases of erythraemia which end in anaemia. With these latter cases may be compared those of Banti's syndrome, which, having a raised blood count, are entitled justifiably but paradoxically "anaemia splenica sine anaemia." The knowledge that cirrhosis is generally accompanied by some form of anaemia, occasionally by a grave form not attributable to gastro-intestinal haemorrhage, lends interest to the syndrome in which hepatic cirrhosis is associated with erythraemia, especially as the remarkable effects of liver treatment in pernicious anaemia would suggest that cirrhosis is not likely to cause polycythaemia. It is conceivable, as was suggested by Levi in regard to a case treated for eighteen months with phenylhydrazine, that the explanation for this exceptional combination may be that erythraemia can cause hepatic cirrhosis by providing in increased quantities the products of the destruction of red cells. On the other hand, as the authors point out, the toxic influence of phenylhydrazine on the liver cells must be taken into account. Gaisböck's polycythaemia, or the association of a raised blood pressure with a high red count, and, usually, the absence of splenic enlargement, has given rise to considerable discussion. The authors would separate this condition from erythraemia; they consider that polycythaemia is commoner than is usually thought in patients with hypertension—indeed, that it may, by diminishing to some extent the work of the heart, be beneficial in high blood pressure. In a section on treatment they consider the possibility that splenic substance by causing anaemia might exert a favourable effect in erythraemia. In view of the good results of splenectomy in chronic haemolytic (acholuric) jaundice, it may be

[1] *Polycythaemia, Erythrocytosis and Erythraemia (Vaquez-Osler Syndrome).* An Epitome based on Parkes Weber's Book of 1921 and the Recent Literature of the Subject. By Parkes Weber, M.D., F.R.C.P., and O. B. Bode, M.D. London: H. K. Lewis and Co. 1929. (3s.)

argued that hypersplenism—a term suggested by Dr. Parkes Weber for excessive functional activity of the spleen—would cause anaemia. A spleen diet, however, has so far been tried only in a few cases, and the results are not consistent. In one case of erythraemia thus treated by the authors there was actually a rise in the red blood count. It may be seriously questioned if splenic substance orally administered is likely to act in the same way as a living spleen in the body.

RAMÓN Y CAJAL.

IN a comprehensive essay-review, which in its manner recalls in some respects the *Critical and Historical Essays* of Macaulay, Lieut.-Colonel F. H. Garrison, librarian of the Surgeon-General's Office of the United States Army, has given a most interesting account of the life and work of Ramón y Cajal,[1] based on the second edition of the great Spanish histologist's biography. Born on May 1st, 1852, at Petilla, Santiago, Cajal was far from a model schoolboy. His teachers, it appears, did not approve his habit of ridiculing their pedantry and caricaturing them on the schoolroom walls; indeed, on one occasion he was committed to prison for his attacks on the scholastic profession. Among his aphorisms collected by Colonel Garrison the following bears on his early experiences: "Those who have not been a little wild in youth are in danger of being so in age, excepting always the mentally defective, the weak-willed, and the prematurely old." His father, who did not always manage him successfully, introduced him to osteology, even taking a hand in robbing ossuaries to secure the requisite material; and as a result Cajal now used his talent for drawing to such good purpose that his father was anxious to publish an anatomical atlas comprising his son's coloured sketches. Graduating in medicine during the early seventies, Cajal entered the Medical Corps of the Spanish Army, and served in Cuba. In 1878 he had a severe haemoptysis, and a year later, against everyone's advice and with the happiest results, he married. During the cholera epidemic of 1879 Cajal, then professor of anatomy at Valencia (an appointment he had received in the previous year), was the first in Spain to establish, by a staining method of his own, the causal relation between cholera and Koch's comma bacillus. His improvement of Golgi's chrome silver stain enabled him to carry out his classical work on the structure of the central nervous system; his findings, at first received with scepticism, soon carried conviction, and it was in tribute to his work that he was chosen to deliver the Croonian Lecture at the Royal Society in 1894, and was made the recipient of several great prizes, including a share with Golgi of the Nobel Prize in 1906. In the course of his academic life he realized his early ambition of founding a school of Spanish histologists, and when he retired in 1922 his laboratory became known as the Institute Cajal. As well as anatomist and artist, Ramón y Cajal was a philosopher and writer, and from his purely literary work Colonel Garrison quotes a number of aphorisms tinged with Latin pessimism, from among which we reproduce the following: "Let us look on men with systematized minds as on books; they are read if interesting, but no one argues with them."

LADY ALMONERS' REPORTS.

IT is a pity that the charming title "lady almoner" should be associated with institutions for which no better appellation than "social service departments" has been found. The phrase suggests an age of petrol pumps! With the work, however, of the lady almoner no fault can be found, and its value is well indicated by the reports of the departments at St. Thomas's Hospital and at the Royal London Ophthalmic Hospital for the year 1928. At St. Thomas's Hospital Miss A. E. Cummins, O.B.E., has now retired from her post, after twenty-five years as a pioneer lady almoner; her experienced advice and help have been instrumental in the creation of similar departments in other hospitals. Apart from inquiring into the circumstances of patients, to see how far help is needed to render hospital treatment of permanent benefit, and how far patients can help the hospital, these departments provide convalescent facilities, instruments, transport, and help which may range from a pair of curtains for a draughty bedroom to emigration of a whole family to a Dominion. The St. Thomas's Hospital almoner's report, which includes, as usual, an account of the activities financed by the Northcote Trust, gives details of many patients who have been helped in their difficulties. It is noted also that careful watch is to be kept on the effect of the new Local Government Act on the work of the department. The social service department at Moorfields Eye Hospital is of more recent origin, and was started in October, 1920. In her report Miss M. W. Edminson states that the extension of the Old Age Pension Act to insured persons over 65 has not proved an unmixed blessing, since, if a pensioner who still continues to work falls ill, he is no longer entitled to sickness benefit, but is only eligible for the much smaller allowance of 10s. a week. In the "follow-up" work of the department it has been found that there is a great decrease in the number of infants requiring care for ophthalmia neonatorum. This is attributed in part to the increased efficiency of midwives, and to general education in maternity and child welfare. In both reports an appeal is made for increased subscriptions to the Samaritan funds, the financial position of which is causing considerable anxiety.

ROYAL SOCIETY OF MEDICINE.

THE officers of the Royal Society of Medicine have decided to continue the holding of special discussions during the session 1929–30. The following subjects have been chosen for joint discussions between two or more Sections, the dates to be settled later and announced on the society's diary card: (1) causes of early abortion and sterility; (2) the position of radium in the treatment of gynaecological conditions; (3) the difficult child; (4) the therapeutic value of gold compounds—sanocrysin, etc.; (5) diseases of the pituitary body; (6) actinomycosis common to man and animals; (7) undulant fever common to man and animals; (8) tropical diseases arising from dietetic deficiency. The annual dinner of the society will be held at the May Fair Hotel on Thursday, November 21st, with the president, Lord Dawson of Penn, in the chair.

THE MEDICAL REGISTER: UNTRACEABLE PRACTITIONERS

WE publish in the *Supplement* this week (p. 155), at the request of the Registrar of the General Medical Council, a list of the names of those medical practitioners who have not replied to his inquiries as to the accuracy of their postal addresses. Any practitioner whose name is included in this list should communicate at once with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, or, in certain specified cases, with the Registrar of the Scottish Branch Council, 12, Queen Street, Edinburgh.

THE Schorstein Memorial Lecture will be delivered by Dr. Arthur F. Hurst, senior physician to Guy's Hospital, on Friday, November 8th, at 4.30 p.m., in the Bearsted Clinical Theatre of the London Hospital Medical College. His subject is "Precursors of carcinoma of the stomach." Members of the profession are invited to attend.

WE regret to announce the death, on September 22nd, of Dr. Ernest Glynn, formerly professor of pathology in the University of Liverpool. An obituary notice will appear in an early issue.

[1] Garrison, F. H.: *Bull. New York Acad. Med.*, 1929, Sec. Ser., v, 483–508.

TRAINING AND EMPLOYMENT OF MIDWIVES.

THE DEPARTMENTAL COMMITTEE'S REPORT.

IN May, 1928, Mr. Neville Chamberlain, as Minister of Health, appointed a departmental committee "to consider the working of the Midwives Acts, 1902 to 1926, with particular reference to the training of midwives (including its relation to the education of medical students in midwifery) and the conditions under which midwives are employed." Sir Robert Bolam was appointed the chairman of this committee, and the other members included six more members of the medical profession—a senior medical officer of the Ministry (Dame Janet Campbell), three members of the public health service (Drs. W. A. Daley, Eustace Hill, and F. N. Kay Menzies), an obstetric consultant (Dr. J. S. Fairbairn), and a general practitioner (Dr. J. W. Bone). The other members were Mr. A. B. Maclachlan, an officer of the Ministry, Lady Cynthia Colville, Mrs. Bruce Richmond, Miss Alice Gregory, Miss K. Stephenson, and Mrs. E. Barton. The report is signed by all the members, but a very important reservation is made jointly by Dr. Fairbairn and Mrs. Richmond. Apart from the substantial point of their reservation, which will be dealt with later, they complain of the conduct of the proceedings of the committee being such as not to have allowed adequate discussion and consideration of the point in question, and also (in their final paragraph) of the personnel of the committee itself. The propriety of these two criticisms appears to be open to question.

The report of the committee should be read in close connexion with the Memorandum of Evidence submitted by the British Medical Association (*Supplement*, April 20th, 1929, p. 122) and the Association's National Maternity Service Scheme (*Supplement*, June 29th, 1929, p. 258—slightly amended at the Representative Meeting, and published as an Association document).

The report opens with a short historical survey of the position prior to the passing of the Midwives Act, 1902, and of subsequent legislation and administration up to the passing of the corresponding Act of 1926. There are a few points, relatively minor, in regard to this legislation and administration which are still, from time to time, the subject of complaint or criticism by the medical profession. Some of them are mentioned in the Memorandum of Evidence submitted by the British Medical Association, and it may be as well to note the way in which these matters are dealt with by the departmental committee. It has been contended that the scale of fees payable to doctors called in by midwives is faulty in at least two respects—first, that the fee of two guineas for attendance at an abnormal confinement is too low, and secondly, that no fee is payable after the expiry of four weeks from the day of birth, even if the doctor is summoned by the midwife, by the use of the official form for this purpose. The committee recommends that the scale of fees should be reconsidered by the Minister in consultation with the local supervising authorities and the British Medical Association. Further, the doctor is statutorily required to submit his claim for such fees within a period of two months from the date on which he was called in. This is really a matter of small moment, but it no doubt causes a certain amount of inconvenience to some, and it has been stated that a period of three months would allow the rendering of the account to be a matter of routine instead of one which required special attention. The committee recommended that this alteration of time should be made. Again, there has been in a few counties some irritation in connexion with schemes under which an expectant mother can, in accordance with the Midwives Act, 1926, by prior payment of an agreed sum, insure against the liability for the payment of a doctor's fee. Such irritation as has been aroused has apparently been due rather to the circulars or administrative methods of the medical officers of health concerned than to the principle of an insurance arrangement. As the committee points out, the establishment of a national maternity scheme on proper lines would do away with the need for any such local provisions.

Two other points of a somewhat similar nature may be mentioned here. The delay in the payment of the cash maternity benefit to insured persons by approved societies is acknowledged to be sometimes considerable, and seriously disadvantageous to the mother. Not only does this result in very late payment of the midwife's fee or of the expenses of an institution in which the confinement has taken place, but it may prevent the securing at the proper time of that very extra comfort or nourishment which the benefit was designed to provide. The committee merely states that "it is obviously important that the appropriate fee should in every case be paid with expedition," and there is no evidence in the report of consideration of the British Medical Association's suggestion that, under due safeguard by medical certificate, half the amount of the benefit might be payable a short time prior to the confinement. This suggestion may still, however, be commended to attention. In its Memorandum of Evidence the Association further drew attention to the fact that, though the rules for midwives stated that "in calling in medical assistance the midwife shall send for the registered medical practitioner desired by the patient, or, if the patient cannot be consulted, by the responsible representative of her family," the spirit of this requirement is often evaded by midwives who, instead of giving the choice freely to the patient, induce her or her friends to send for some doctor favoured by the midwife herself. There is definite evidence of such practices, which naturally prevent in some cases that real collaboration between midwives and doctors which is absolutely essential in the public interest. The committee makes no reference to this matter, probably on the ground that no alteration of the rules is required, and that the remedy is to be sought rather in the direction of those who are in a position to influence the conduct of midwives, urging them to loyal observance. There is certainly need for such influence being exerted. With regard to actual alterations of the rules, the suggestions of the Association are practically endorsed *in toto*. It may not be amiss, however, to reiterate that among the stated examples of abnormality there should be included albumin in the urine, however slight, and breech presentation, even uncomplicated.

The main body of the report deals with three large matters: (1) the training and conditions of employment of midwives; (2) the composition and functions of the Central Midwives Board; (3) a national maternity service.

TRAINING IN RELATION TO CONDITIONS OF EMPLOYMENT.

The conditions of employment of midwives (including the remuneration that can be earned), and the training that should be required, are interdependent. No doubt the status of the calling has been raised during recent years, and its disadvantages somewhat diminished; but unless better financial prospects can be offered to women of suitable type and education, whether they practise as independent midwives or as members of the staff of nursing associations, maternity institutions, or local authorities, such women will not enter it, and it will be difficult to insist upon the full and adequate training that should be required or upon such tests of the result of that training as should be applied. It is true that "the midwife occupies an exceptionally responsible position in the life of the community compared with women employed in the allied branches of the nursing profession since she is directly answerable during the normal course of her everyday work for the lives of two patients, mother and child"; but the difficulties and disadvantages attaching to midwifery practice are set forth in the report with convincing eloquence. As regards earnings, the committee says: "We learn that the earnings of the independent midwife vary from £30 to £275 per annum, and that a large number of whole-time workers, excluding those who merely practise intermittently and derive their main income from other sources, earn only from £90 to £120 per annum. There is naturally a limited number who succeed in earning more: one stated in evidence that her income was approximately £350 a year. . . . In certain areas local authorities employ whole-time salaried midwives, and in others they pay fixed subsidies to certain midwives, while in a few cases they guarantee minimum

salaries to selected independent midwives. In the first group salaries range from £150 to £250 inclusive, *plus* civil service bonus. In the second group midwives are paid a fixed subsidy, in one case as low as £10 and in another case as high as £80 a year; under these arrangements the midwife retains her fees, but is not required to account for them. In the third group the guaranteed salary varies from £120 to £230 a year. The midwife in this group is allowed to keep her fees, but is required to account for them to the local authority." In these circumstances improvements in the requirements for training cannot be drastic or sudden, nor can those in the conditions of practice be other than gradual. The latter, it is indicated, are to be sought in a more extended and better organization of the work of nursing associations, including a superannuation scheme, the elimination of the uncertificated woman as a maternity nurse, especially in certain areas where custom and tradition make her influence unusually strong, the discouragement of casual and intermittent practice, and, above all, in the establishment of a national maternity service, which would allow of the employment of an increased number of midwives at more adequate rates of remuneration. With regard to such rates the report says, "We are of opinion that the fee of 30s. suggested in the Majority Report of the Royal Commission on National Health Insurance is quite inadequate, and we trust that it will be immediately possible to secure a sufficiently substantial increase in the earnings of the average midwife by the institution of a considerably larger fee." It may be remembered that the tentative fee taken for purposes of calculation in the scheme of the British Medical Association is 50s., and this on the supposition that about 110 cases a year can properly be undertaken. On this last point the committee expresses the opinion that the number "should not greatly exceed 100 cases per annum." The alterations suggested in training are mainly (1) the restriction of the age of entrants, fixed by reference to the time of commencing training, to the ages of 20 years to 40 years; (2) the institution of an entrance examination "of an elementary kind the syllabus and standard of which should be laid down by some central body, to ensure that the candidate is able to fill in [illegible] to understand weights and measures, [illegible] and to profit by the instruction that she will receive in the science of her future profession: for this purpose it would probably be sufficient if the examination were to be restricted to such subjects as reading, writing, spelling, and dictation, and simple arithmetic"; and "it is desirable that the examination, which should be held in all parts of the country, should be placed in the hands of the local education authorities"; (3) the institution of a clinical examination as part of the final test for certification; (4) a period of three months' compulsory post-examination experience, to be undertaken within six months of passing the examination, the midwife being responsible personally for the conduct of labour in not less than five cases during that period.

In connexion with the training of midwives several other matters, incidental but of considerable importance, are considered. The more important conclusions are (1) that there should be no minor course or test for women who propose to become not midwives but maternity nurses only; (2) that a prescribed examination for non-medical teachers of midwifery should be instituted; (3) that as regards the shortage of clinical material, "some restrictions upon the training of pupil midwives in hospitals attached to medical schools are necessary," and that "students in a medical school area should have preference in the apportionment of material, and that pupil midwives should be allowed to make use of such material only in so far as it is in excess of the needs of medical students"; (4) that facilities for post-certificate training should be encouraged and arranged for midwives at regular intervals by all local supervising authorities, and that the cost incurred, together with midwives' expenses and any expenditure that might be involved in the provision of a locumtenent should be borne by these authorities; and that such post-certificate training might be made obligatory upon those midwives whose practice is very small or intermittent.

Under the heading of "supervision of midwives" the committee notes that "the arrangements for inspection vary widely," and enumerates a number of these arrangements, many of them involving the use of health visitors as inspectors. With regard to this it says, "The employment of health visitors with little or no practical experience of midwifery for the purpose of inspecting midwives is wrong, both in conception and principle, and is strongly to be deprecated." It gives valid reasons for this expression of opinion, and recommends that "every new appointment to the post of chief inspector of midwives should be given to a medical officer who has had actual experience of obstetric practice and who is engaged in other work of a similar nature—for example, as an assistant medical officer for maternity and child welfare—" and that "subordinate posts for routine inspections should be filled, as and when vacancies arise, by midwives who hold the general nursing qualification and have gained experience in the actual practice of midwifery over a prolonged period."

THE COMPOSITION AND FUNCTIONS OF THE CENTRAL MIDWIVES BOARD.

The report proposes considerable changes both in the composition and in the functions of the Central Midwives Board. These functions may be said at present to be fourfold: (1) disciplinary and judicial; (2) the approval and inspection of training institutions and teachers; (3) the determining of the conditions of entry into the calling, and the course, length, and character of the training to be undergone; (4) the holding of a qualifying examination. With regard to the first of these it may be said briefly that the proposals of the committee would assimilate the powers and proceedings of the Board to those of the General Medical Council, with this addition: that it is recommended that the Board should have power to subpoena witnesses and to require evidence on oath and the production of documents. With regard to the fourth class of function, that of examination, it is stated that "there is much to be said for keeping it apart, both in personnel and association, from the judicial functioning of the Board. To this end provision should be made for the Board to appoint an Examination Board, which should be directly answerable to the Central Midwives Board for the conduct of its duties."

An acute and important difference of opinion arises in regard to the second and third of the classes of function as stated above. The majority of the committee propose that they shall be transferred, *en bloc*, to the Minister of Health, who should have the assistance of an Advisory Committee. They set out their recommendations thus:

Approval of Training Institutions and Teachers.

(58) That the existing arrangements for the approval and inspection of training institutions and teachers by the Central Midwives Board are unsatisfactory by reason of their extremely limited scope, and that the whole of this work should be placed in the hands of the Minister of Health, on whose behalf the majority of the institutions recognized as training schools by the Board are at present inspected by officers of his department, either in connexion with grants in aid of midwifery services or the training of midwives, or as part of the routine inspections of Poor Law institutions.

(59) That an Advisory Committee, consisting of persons appointed by the Minister of Health on the nomination of representative bodies (including the Central Midwives Board) should be formed to advise the Minister regarding matters coming within the scope of his inspecting and approving duties.

Course and Length of Training.

(60) That it is inadvisable that separate bodies should be responsible on the one hand for the approval and inspection of training institutions and teachers and on the other hand for laying down the training curriculum, and that the duty of formulating the course and length of training should also pass from the Central Midwives Board to the Minister of Health who, with the assistance of the Advisory Committee referred to in (59), would decide from time to time what alterations in the curriculum are necessary to meet changing conditions.

The argument leading up to these recommendations is contained in paragraphs 100 to 104 of the report, and these should be carefully considered. Dr. Fairbairn and Mrs.

Bruce Richmond dissent strongly from these conclusions, and their main case is set out in certain paragraphs of their joint reservation, thus:

"The determination of the duration and character of training, the approval of schools and teachers and the examination of candidates are not only all closely linked together, but form an integral part of the work of the Board, which formulates the rules under which the midwife works, determines the conditions under which she practises, adjudicates on charges of professional misconduct, and keeps and purges the roll. These functions are so interrelated that they should be retained in the hands of a single authority. The hearing of penal cases provides evidence of when and where alterations in rules are called for, and gives information as to deficiencies in the education and training of midwives. In conducting the examinations, the candidates' schedules sent up from training schools and reports by examiners reveal weaknesses that are not otherwise likely to be discovered. Thus the penal and examining duties are linked up with the curriculum and the approval of schools and teachers, and to leave the former where they are and hand over the latter to another body with some device for liaison between them must be inferior to a unified control. This proposal to break up work that has, in the experience of a generation, been welded into a compact whole, and the distribution of its parts between an attenuated Midwives Board and a department of the Ministry of Health, with an Advisory Committee at its back, makes a dual control (or triple if the Advisory Committee is more than a shadow) that is not likely to draw women into a profession already groaning under a weight of official supervision. . . .

"The committee in its report has expressed itself as anxious to raise the status of the midwife and to make her vocation a real profession that will attract women of better education than it has hitherto done, but its recommendations regarding the Midwives Board appear to be wholly inconsistent with that ideal. It is the general rule for all professions—medical, legal, and others—that they retain in their own hands the decision as to what is the proper training for and means of entry into them. The closely allied nursing profession affords the best analogy. Under the Nurses Registration Act, 1919, the General Nursing Council was constituted to play a part in the governance of the nursing profession corresponding to that of the Central Midwives Board in the midwifery profession, including 'regulating the conditions of admission to the register.' . . . The midwives should have control over their profession at least equivalent to that exercised by registered nurses over theirs, and it is scarcely disputable that a gradual increase in the elected representatives should be the aim, so that both, with some outside help from the medical profession and others, may ultimately be able, as other professions are, to determine conditions of training and entry and to maintain their own professional standards. Anything that lowers the status and prestige of the ultimate authority over them, anything that postpones the possibility of their obtaining the control over their profession that is granted to other professions, must cause deep and bitter resentment among midwives. . . . We would urge that no such momentous changes as those recommended in this report should be made without full and open discussion."

We feel bound to say that on the main point of principle we believe Dr. Fairbairn and Mrs. Richmond to be right. If the calling of the midwife is ever to be raised to the dignity of a profession, it is almost essential, at the very least it is eminently desirable in accordance with the traditions and methods of this country, that it should be preponderantly self-governing; if this be not so the sense of corporate responsibility is not developed, or is at any rate weakened. It is true that a midwives' profession must, in fact, be in some sense a subordinate profession in so far as it will be dependent upon the profession of medicine, and therefore an appropriate part in its governance must be assigned to, and exercised by, medical practitioners. There is undoubtedly some disadvantage in any separation of the last three of the functions of the Central Midwives Board as set out above. But the committee seems to have made out a case for the really practical point of transferring the inspection of training institutions and teachers to the Government department concerned. It is at least as logical to separate this function from the other two as to separate this and the third together from the duty of examination, and in fact both logic and experience seem to indicate that, if separation of function there is to be, it is here that it can be made with least ill effect. The committee, so far as its report is evidence, has really made no attempt to justify the transfer of the third set of functions from the Board to the Minister. Its desirability is not self-evident, yet in paragraph 104 and conclusion 60 it seems to be assumed that this is so, for not a single reason is given. As to the constitution of the Board, if the transfer of functions, as we hope, be not so drastic as that recommended in the report, the number of members would probably require to be a little larger than that *suggested by* the committee, but there is no reason why the method of appointment should be varied. The recommendation on this point is that the Board should be constituted as follows:

> (*a*) Three members elected by vote of the midwives on the roll who have given notice of their intention to practise during the year preceding the election.
>
> (*b*) Two members jointly nominated by the County Councils Association and the Association of Municipal Corporations, one of whom should be a medical officer of health and one a member of a local *supervising authority*.
>
> (*c*) Two members—registered medical practitioners—nominated by the British Medical Association, one of whom should be in general practice and one an *obstetric specialist*.
>
> (*d*) Two members nominated by the Minister of Health, one of whom should be a *mother who is neither* a certified midwife nor a registered medical practitioner.

Members of the Board might serve for a period of five years and be eligible for re-election or re-nomination, as the case may be.

A National Maternity Service.

That part of the report which deals with the need for a National Maternity Service scheme, with the principles on which it should be based, and with the chief details of the arrangements which it must necessarily embody, is exceedingly valuable and interesting. These features of the report, however, do not require any full description here, inasmuch as they are, in effect, almost identical with those of the scheme prepared by the British Medical Association, and published and commented upon so recently in the *Journal*. The Association's scheme is the more detailed both as to service and as to finance, and if any differences between it and the committee's scheme are to be sought they may perhaps be stated as follows. The latter suggests that when a woman engages a doctor as well as a midwife in a normal case, there shall be a State contribution towards her expenses, whereas the Association's scheme provides the woman as *part of the insurance* arrangement with what is *essential, and leaves her to* provide the rest privately. There would probably be little difference in the cost to the patient in the two cases, but we believe that the Association's method, partaking less of the nature of a dole, is preferable. Again, the committee's scheme enlarges the need for institutional provision, as it leaves to the woman the option of going into the institution for reasons of personal convenience as well as for medical necessity. Further, the committee believes that there may be some 70,000 cases of necessitous persons who will not be within the ambit of the insurance scheme, and who, therefore, must be dealt with on other, though analogous, lines. The Association prefers that some method should be found (and some such methods are indicated in its Memorandum) by which such cases could be brought within the service.

Miscellaneous Points.

One or two miscellaneous matters remain for mention. Certain paragraphs on ante-natal clinics are of interest.

84. Ante-natal clinics are becoming very popular in certain parts of the country. Two kinds of work go on there—the medical and the non-medical or social. The medical consists of examination by a doctor with a view to detecting abnormalities and making appropriate arrangements, generally by reference to a private doctor or a maternity hospital, to ensure that the confinement will be as safe as possible. The non-medical work consists of instruction in motherecraft, including the clothing and feeding of infants, the giving of hygienic hints on healthy living for expectant mothers, and following up the doctor's advice by, for example, the supply and application of bandages for varicose veins and the treatment of constipation. A number of women would, doubtless, prefer to attend these clinics for medical examination, despite the arrangement proposed in this report under which every expectant mother coming within the scope of the National Health Insurance Acts would have the services of a private doctor for ante-natal examination; and, subject to the consent of the doctor responsible for treating any emergency which might arise in the course of the confinement, there would seem to be no objection to the patient attending such a clinic, provided full co-operation of the clinic with the doctor were ensured.

85. In cases of this kind the medical portion of the ante-natal record form, to which reference is made in paragraph 46 and Appendix B, would be completed by the medical officer of the clinic, but care should be taken to ensure that both the midwife and the private doctor are acquainted fully with the information gained by the medical officer of the clinic regarding the health of each pregnant woman whom he or she examines. This end would best be achieved, so far as the midwife is concerned, if she were encouraged to accompany her patient to the clinic in order that she may be present when the medical examination is made. Such an arrangement would be of great value to her from an educational point of view. The midwife should be treated by the clinic staff as a professional colleague. If any private doctor has sufficient patients to warrant the holding of a special session, the local authority might allow him, on agreed terms, to have the use of the authority's clinic and nursing staff, so that he may see his patients there.

On the controversy as to whether midwives should be allowed to administer sedative drugs entirely on their own responsibility, the committee says: "There can be no absolute ban because of occasional emergencies when the services of a doctor are not available. At the same time, if the well-being of the mother be the prime consideration midwives cannot be regarded as persons fitted either by training or experience to be given complete freedom in the use of drugs. We feel bound to place on record that the midwife is not the person on whom, in the ordinary course, the responsibility for the administration of hypodermic injections—for example, of morphine or pituitrin—should lie." There is a recommendation "that steps should be taken to secure the notification to the appropriate medical officers of health of all cases of pemphigus neonatorum"; and an expression of opinion "that it would be in the public interest if some professional body would take upon itself the responsibility for issuing at an early date some pronouncement as to the advisability and place in labour not only of anaesthetics but also of analgesic and sedative drugs generally."

THE THIRTEENTH INTERNATIONAL PHYSIOLOGICAL CONGRESS AT BOSTON.

[FROM A SPECIAL CORRESPONDENT.]

THE thirteenth meeting of the International Physiological Congress possessed unique interest, in that it was the first of these congresses to be held in America, and the interest actually aroused is best indicated by the fact that it was attended by 1,400 persons, whereas the previous largest attendance—at the twelfth congress at Stockholm in 1926—had been only 650. These triennial congresses have maintained a remarkably high level of popularity for forty years, and their success has undoubtedly been due to the principles enunciated when the first congress was suggested by a group of English physiologists. These principles were that the purpose of the congress was for the international interchange of ideas, and that the communications should be as little formal and as fully demonstrative and experimental as possible. Twelve congresses have since been held in European towns, but three years ago it was agreed to accept the invitation of the Federation of American Societies for Experimental Biology and to hold the thirteenth congress in Boston. At that time the advisability of the new departure was doubted by many, but the optimists declared that an attendance of nearly 200 European physiologists might be expected. The actual attendance greatly exceeded all expectations, for there were about 700 foreign delegates, of whom more than 500 came from Europe. Indeed, the number of European delegates to Boston was actually greater than the corresponding number at the Stockholm congress in 1926.

A Well-organized Congress.

All those who have any acquaintance with congresses will realize at once the dire consequences that often ensue when attendance completely outruns all expectations. Therefore it is as well to say at once that the organization of the congress was an unqualified triumph. Everything ran as if by clockwork, and every day and at every turn the guests met fresh evidence of the meticulous care and forethought that had been exercised to ensure their comfort. The open-handed hospitality of the people of the United States is traditional, and the hospitality received exceeded expectation; but what still more impressed the guests was the enormous amount of work that must have been done in order to produce such perfect success in organization. The congress was favoured with excellent weather, but the general feeling was that no vagary of weather would have been able to upset the arrangements organized by our Boston hosts.

Thirty-five nationalities were represented at the congress, and among the delegates were many noted veterans, such as Ivan Petrovitch Pavlov, now in his eightieth year, Léon Fredericq, who was president of the second international congress at Liège in 1892, E. Gley of Paris, and Hans H. Meyer of Vienna. The especial value of international congresses is that they afford an opportunity for workers of different nationalities to establish personal contact, and the present congress fulfilled this purpose with striking success. For many members the congress commenced directly they left Europe, since no fewer than 370 physiologists crossed on one boat. Moreover, after the congress a large proportion of the European guests were entertained in Toronto and Montreal. The social side of the congress was therefore developed to an exceptional degree, thanks to the hospitality so freely offered in the United States and in Canada.

The Wide Field of Physiology.

The congress proper opened on Monday evening, August 12th, and the sessions continued during the ensuing four days. There were about 450 communications and 75 demonstrations. This large agenda was carried through by dividing the congress into six sections, and by limiting communications to ten minutes and discussions to five minutes. The number of the communications, although impressive, scarcely indicates the great mass of work reported upon, because the communications were mostly summaries, reduced to the briefest terms, of a large amount of work. Consequently it is impossible to do more than mention a few of the communications that appeared to have a special medical interest. Speaking generally, one may say that there were few sensational discoveries reported, but that the communications, *en masse*, gave evidence of a steady advance of physiological science over a wide front. In all sciences the nature of the progress made varies from decade to decade; there are periods during which pioneer work opens up great new fields of knowledge, whilst such periods of rapid advance are usually followed by periods of consolidation, during which the new territory is thoroughly explored and organized. Just at present physiology appears to be in the latter stage, and the general nature of most of the communications was the reporting of accurate information concerning fields of knowledge that had already been partially explored. Although work of this nature is not so sensational as advances in new fields of knowledge, yet its value for medical science is particularly great because physiological discoveries usually require to be thoroughly worked out before they can be applied in the treatment of disease.

Professor Krogh gave the opening address to the congress, and chose as his subject "The future of physiology." He pointed out that it was now beyond the power of any human being to keep in touch with the progress of physiology in all its branches, both on account of the overwhelming mass of the literature and also on account of the extreme diversity of the subjects with which the different branches were concerned. The list of communications delivered at the congress fully bore out the validity of these propositions. Their mass was double that of the last congress and treble that of the Edinburgh congress of 1923, and the increase in diversity was proportional to the increase in mass. The communications presented to the congress represented in fact an enormous mass of work, involving most of the branches of chemistry and physics, and touching on other sciences such as genetics and psychology. A considerable proportion of the communications dealt with biochemistry, and, in particular, there were interesting discussions on the vexed question of the chemical changes associated with muscular contraction. The solution of such fundamental problems is essential for the advance of physiology, but their importance to medicine

is indirect rather than direct. The advances reported in endocrinology and vitaminology have, however, a more direct interest for medicine. A very large amount of work has been done in recent years on the ovarian hormones, and advance is slowly being made in this difficult subject.

Advances in Endocrinology.

Doisy, Veler, and Thayer reported improved methods for isolating folliculin, which enabled them to isolate from the urine of pregnant women preparations, of which one rat unit weighed less than 0.001 milligram. McClendon and his co-workers investigated the clinical action of this hormone. They gave doses up to 4,000 mouse units, and found that these produced a rise in the metabolism of women, and could induce menstruation in women suffering from amenorrhœa of considerable duration. The preparation of active principles from the testis has proved a more difficult problem than the obtaining of active principles from the ovary. Koch, Moore, and Gallagher stated, however, that they had obtained a lipoid extract from bull testicles which, when injected into capons, caused a growth of comb, and when administered to castrated rats and guinea-pigs corrected several of the effects of castration. Voronoff also reported the effects of testicular grafts, and claimed that the effects of such grafting continued for five years. He showed histological sections which he claimed proved that the grafted cells survived for about three and a half years.

Important advances were also reported regarding knowledge of the functions of the anterior lobe of the pituitary gland. Cushing and Teel showed that at least two principles were present—the growth and the sex principle. Administration of the growth principle to dogs caused a pathological overgrowth, which resulted in peculiar deformities and at the same time caused hyperplasia of the thyroid and the adrenal cortex, together with amenorrhœa in females and testicular atrophy in males. The sex principle produced premature œstrus in rats and caused enlargement of the ovaries. This work confirms the opinion that the anterior lobe of the pituitary resembles the posterior in that both contain a number of separate active principles of great importance.

Koehler and Eichelberger described a method for separating from the suprarenal glands a new active principle. This substance, when administered to cases of myasthenia gravis, caused a rise in metabolic rate and a still greater rise in mechanical efficiency. Rogoff and Stewart also reported that they had obtained from the suprarenal cortex an active principle, which they named interrenalin, the administration of which caused a marked prolongation of life in suprarenalectomized animals. These reports indicate that slow but definite progress is being made in elucidating the important problems of the nature of the endocrine functions of the sex glands, the anterior pituitary, and the suprarenal cortex.

Vitamins: Irradiated Ergosterol.

Coward, Key, and Morgan reported the existence of a new growth-promoting vitamin, which is necessary for growth to maturity, but which is distinct from the six vitamins hitherto identified. The fact that excessive doses of cod-liver oil or of irradiated ergosterol can produce toxic effects has naturally led to extensive investigations on this important subject. Unfortunately the results reported are somewhat discrepant. Seel found that prolonged ultra-violet irradiation of ergosterol in alcoholic solution caused the production of definitely toxic substances. Agduhr found that cod-liver oil could produce toxic effects and that the therapeutic doses of cod-liver oil as recommended in several textbooks were capable of producing lesions in men and in animals. He concluded that the toxic effects were caused by the co-operation of several toxic substances contained in the oil. On the other hand, Bills and his co-workers found that it was possible to produce an irradiated ergosterol that was remarkably non-toxic, and that more than 4,000 times the therapeutic dose of such a preparation was required to produce a hypercalcification.

New Anæsthetics: Drug Addiction.

Various interesting advances in pharmacology were described. Lucas and Henderson reported on the anæsthetic properties of cyclopropane. This gas produced surgical anæsthesia in a concentration of 11 per cent. in oxygen, and appeared to combine a high anæsthetic power with low toxicity. Zerpas, Clowes, and co-workers described the use of sodium amytal (sodium-iso-amyl-ethyl-barbiturate) as an anæsthetic. They concluded that it was a very valuable anæsthetic for intravenous administration. It has been used successfully in more than a thousand human cases. The solution requires, however, to be prepared with very great care, as the salt is easily decomposed and then produces toxic effects.

The problem of the nature of drug addiction is one that has hitherto been neglected, and it is satisfactory to note that it is now being investigated systematically. Barbour and co-workers concluded that morphine habituation was associated with the dehydration of certain organs, and that sudden withdrawal resulted in a remarkable redistribution of water within the body. They suggested that these changes were the cause of the physical symptoms that follow morphine withdrawal. Schmidt and Livingston studied the production of morphine tolerance in dogs, and showed that prolonged administration of small doses produced little tolerance, but that a few large doses were sufficient to produce measurable tolerance.

Ganglionectomy for Arthritis.

One of the communications of greatest direct interest to clinical workers was the report by Rowntree and Adson on the effects of sympathetic ganglionectomy and ramisectomy in arthritis. These authors removed the lumbar sympathetic in an advanced case of arthritis deformans, and this resulted in immediate and complete cure of the arthritis in the lower extremities, a cure which has persisted for three years. The patient was so pleased with the results that she was glad to have a second operation performed two years later to relieve the upper extremities. The removal of the first and second dorsal ganglia and the cervico-dorsal ganglion resulted in an almost complete cure of the arthritis in the arms. The authors concluded that the arthritis was associated with excessive vaso-constriction that was relieved by excision of the sympathetic. They further concluded that the nervous system played a much greater part in the phenomena of arthritis than had hitherto been supposed.

Demonstrations.

One of the general principles governing the international physiological congress is that the communications should be as fully demonstrative and experimental as possible. In accordance with this tradition demonstrations were one of the outstanding features of interest in the congress. Rein showed a very ingenious method of estimating the rate of blood flow through any artery. Diathermy was applied across the artery and the differences in the temperatures above and below the diathermal current were measured. The amount of heat introduced was known, and hence the volume of blood passing could be calculated. E. R. Clark and Sandison showed a method for the study of capillaries in the normal mammal. A double-walled transparent chamber was introduced into a rabbit's ear, and this resulted in a thin chamber whose contents could be studied with the highest powers of the microscope. Downing and Hill showed thermopiles of extreme sensitivity, which were capable of measuring the heat production of nerve. Erlanger and Gasser showed an oscillograph with an amplification of 100,000, by means of which the details of the action currents of nerves could be studied.

Conditioned Reflexes.

An outstanding feature of the congress was the address delivered by Professor Pavlov on the last day, in which he discussed the part played by inhibition in the normal activity of the cerebral hemispheres. Pavlov considered that two roles of the inhibitory process could be distinguished. The first was the protection of the cortical cells from excessive cortical destruction caused by strong stimuli, and the second was the protection of these same cells from useless work. The question whether a single basis could be ascribed to these two roles was an important question still unsolved. According to Pavlov's theory sleep is a result of the spread of inhibition throughout the entire cortex of the brain. Various other communications on conditional reflexes were given, some of which supported Pavlov's theories of inhibition and sleep, whilst others were

opposed to these theories. It is interesting to note that an increasing number of workers are using the technique elaborated by Pavlov for the study of conditioned reflexes, in spite of the extreme difficulty of the method.

It has not been possible to mention more than a tithe of the papers of interest that were presented at the congress. As has been already remarked the outstanding feature of the meeting was the evidence that it provided of the very great amount of research work in physiology that is proceeding at present in all countries throughout the world.

Correspondence.

SURGICAL TUBERCULOSIS.

SIR,—I agree with your insistence in your leading article last week upon the necessity of distinguishing between the treatment of surgical tuberculosis in adults and in children. In the former prolonged periods of purely conservative methods are often utterly futile and sometimes disastrous.

I think Mr. Girdlestone has presented an exceedingly logical and helpful view of "surgical" tuberculosis. His persistent references to a primary focus—often unrecognized—are very timely. In adults this primary focus is generally, almost always, indeed, an intrathoracic one. It is for this reason that the advisability of general anaesthesia in operating on adults with surgical tuberculosis should always be pondered with the utmost care.

It was recognized by our fathers that amputation of a tuberculous joint often did a great deal of good to a co-existing phthisis. When we have exhausted the advantages of modern methods of treatment we are finding it still true to-day, and this operation should be undertaken more frequently in adults in cases where excision is not feasible.

Finally, may I just underline Mr. Girdlestone's reference to the lack of logic on the part of those who would discharge a patient sooner, merely on the ground of a radical operation having been performed, forgetting that all they have done has been with the object of enabling the patient to deal more successfully with his primary lesion.—I am, etc.,

Liverpool, Sept. 23rd. JOHN T. MORRISON.

ABDOMINAL SEPSIS AS A CAUSE OF EYE DISEASE.

SIR,—Dr. T. Harrison Butler's letter in the *Journal* of July 20th (p. 122) pointing out the gall-bladder as a source of infection in eye disease is of great interest. In Bengal a large proportion of cases of chronic cyclitis, episcleritis, primary and secondary glaucoma, choroiditis, and optic atrophy unyielding to local treatment are found associated with intestinal infections by protozoa and flagellates, and nearly always accompanied by a chronic colitis. In these cases the Wassermann reaction is negative, and the teeth, throat, and nasal sinuses are healthy. The addition of effective anti-amoebic therapy to the local treatment has procured, in many cases, relief, arrest, or cure of the ocular condition, suggesting a direct relation between the ocular disease and the effects of the intestinal parasitism. The relief which follows emetine treatment in cases of amoebic iritis is sufficient proof that it is traceable to the large intestine. The occurrence of abdominal discomfort with exacerbations of chronic ocular disease, such as irido-cyclitis and glaucoma suggests an intestinal origin in many of these cases. Corneal ulcers, episcleritis, and keratitis often occur in association with mixed infections in which trichomonas, giardia, and chilomastix predominate. The exudation accompanying chronic plastic iritis of protozoan association develops into a dense membrane, like a Jacksonian membrane, about the caecum and colon which is believed by many to arise from protozoan activity. Arrest of the cyclitic membrane is often caused by anti-amoebic treatment, proving, when no other focus of infection can be found, that its causation is intestinal. The establishment of an association between general disease and eye lesions is often more or less guess-work, when the particular organism has never been found in eye tissues. The benefit obtained from therapeutic tests, however, especially when the result is lasting, should make us less tardy in accepting the significance of such an association.

In ocular complications due to amoebiasis and other protozoal diseases of the caecum and colon, it may be possible that the path for the entrance into the blood stream of other micro-organisms, such as staphylococci and streptococci, is opened up by the lowering of the vitality of the patient and by the local infection, and that these bacteria settle in the uveal tract, and produce inflammation.—I am, etc.,

E. W. O'G. KIRWAN, F.R.C.S.I.,
Professor of Ophthalmology, Medical College, Bengal.

Calcutta, Aug. 29th.

THE PROBLEM OF THE UNFIT.

SIR,—Dr. A. F. Tredgold's admirable letter on this subject, which was published on September 7th (p. 475), points out and emphasizes the incompleteness of the present outlook of the public health services on the life and growth of the individuals comprising the nation. This outlook is concerned with the soil and not with the seed, and when one considers the crop that is being produced—vide Dr. Tredgold's *figures—there must be great uneasiness of soul* and a feeling that all is not well, in spite of declining mortality rates.

In my little book *Observations on Human Heredity* I have made the suggestion that the members of the public health services should consider the aspect of heredity as well as environment, and endeavour to investigate and record such hereditary diseases and abnormalities as present themselves in their daily work as school medical officers or medical officers of institutions or welfare centres. Dr. Tredgold's classic work on mental deficiency could serve as a guide, even if observations were not confined to this—the most important of all transmitted defects. As Dr. Tredgold points out, the profession cannot shelve its responsibility in this vital matter. There is no other body competent to undertake it; but simply because it is difficult, complex, even hazardous—from the point of view of rousing strong feelings—we cannot shun it and maintain our self-respect.

The public health service itself is beginning to move. At the lectures given to the public in this town during Health Week, 1927, there was an excellent lecture on inborn characters by the secretary to the Eugenics Education Society. How far the significance of the lecture was appreciated by the audience I cannot say; to me it showed itself as the beginning of a *reorientation* of the outlook of State medicine.

The Council and Divisions of the Association may not consider the time ripe to appoint a committee of inquiry on this problem, but the Association cannot stand aside altogether and let other professional bodies take the lead.—I am, etc.,

Warrington, Sept. 8th. J. S. MANSON.

SPLENECTOMY FOR SPLENOMEGALIC POLYCYTHAEMIA.

SIR,—It has been generally acknowledged that on *theoretical grounds*, and by the evidence of actual experience, splenectomy is contraindicated for the splenomegaly of true erythraemia ("Vaquez-Osler disease"). Nevertheless, one or two cases have been reported in which splenectomy appears to have done good, as in a case at the Mayo Clinic, recently referred to by Dr. A. F. Hurst in the discussion on the indications and results of splenectomy at the Royal Society of Medicine (*Proceedings*, 1929, xxii, Joint Discussion, No. 9, p. 163). There are, however, various classes of splenomegaly which may occasionally be accompanied by polycythaemia and may clinically simulate erythraemia (Weber and Bode, *Polycythaemia, Erythrocytosis, and Erythraemia*, London, 1929, p. 19)—for instance, cases which may be clinically classed as "Banti's disease or splenic anaemia without anaemia" (*anaemia splenica sine anaemia*). In some such cases splenectomy is probably a rational method of treatment, and apparent exceptions in regard to the result of splenectomy in erythraemia may be explained in that way.—I am, etc.,

F. PARKES WEBER.

London, W.1, Sept. 20th.

CO-OPERATION BETWEEN PRIVATE PRACTITIONERS AND HOSPITALS.

SIR,—Your correspondent Dr. W. M. Penny (September 21st, p. 559) is in error in thinking that the system by which the private medical practitioner is supplied with full details of the in-patient notes of his patient does not already exist. This system was introduced at the Royal Free Hospital about five years ago, and more recently the Cancer Hospital and the Miller General Hospital have both adopted it.

When a patient's case sheet is complete the resident writes the abstract, including the æ-ray and pathological reports. This is corrected, when necessary, by the appropriate registrar, and checked by the honorary medical officer concerned. Four copies are then made: one is sent to the private practitioner; one to the honorary officer for his own private notes; one is bound with the in-patient records; and the fourth attached to the out-patient notes.

This system has been found extremely satisfactory, and we have had many appreciative letters from the practitioners who have benefited from the information supplied.—I am, etc.,

London, W.1, Sept. 21st. CECIL A. JOLL.

SIR,—You have from time to time published in your columns letters critical or condemnatory of the voluntary hospitals' out-patient departments. Your correspondents have found reason to complain, now that their patients, if seen, have been returned without information, now that their interesting clinical material has been permanently appropriated, and that even their daily bread has been jeopardized as a consequence. With the authority of many years as assistant and full physician in London general hospitals, I have more than once been tempted to write in relation to these complaints. I have hitherto refrained, from a reluctance merely to retort and be unable to supply any constructive remedy. But Dr. W. M. Penny's letter in your last issue encourages a sympathetic response, and I hope I may be permitted to encroach on your valuable space.

I often wonder if all general practitioners realize the nature of the material which floods our out-patient departments. Whilst a comparatively small number of cases presenting diagnostic difficulty are sent up for an opinion, including special investigation, the majority are chronic sufferers, generally social misfits. Some are sent to hospital as a convenient dumping ground. In the majority of such cases they arrive without an introductory note of any kind; they have simply been told to go to hospital, an action equally discourteous to the hospital and the patient. An appeal to the almoner by a conscientious physician initiates a wearisome and profitless argument, so that the overworked doctor soon learns to shrug his shoulders and give up protesting. Other chronics arrive on their own account; they find it less expensive to obtain a considerable supply of medicine for a couple of shillings than to continue to attend their practitioners. Most unhappily, hospital boards are too much impressed by the advantage of numbers to sympathize with any suggestion for the drastic reduction of out-patients. At any rate, no out-patient physician is amused at the indictment of voluntarily adding to his burden by encouraging the continued attendance of any individual.

Utilizing the out-patient department (as, of course, it should be utilized) exclusively for consultative purposes, general practitioners very properly expect a report upon any patient sent for an opinion. I estimate that in the course of ten years I have returned patients with such opinions in nearly 2,000 instances. During those ten years I have received less than a dozen acknowledgements. I have long since ceased expecting any expressions of gratitude, and their absence in no way inhibits me from continuing what I believe to be a primary obligation of my office. But I cannot help reflecting that there is some excuse for those of my colleagues who are reproached for their epistolary deficiencies. After all, the patient sent to hospital for a consultation is entitled to precisely the same professional treatment as if he had been sent privately to the consultant's house. But when one recalls that a patient has been seen actually under far better clinical conditions than would have been possible in private, one might expect more evidence of appreciation than is generally forthcoming. We grant that the patient pays his way by providing clinical material from which the hospital physician derives his experience, and upon which he can teach. The consultant clearly pays his way; but the general practitioner, who is so often the complainant, ought to realize that he, too, is a party in the transaction. I am tolerant in remembering that the majority of doctors—all very good fellows—would rather be fined a guinea than write a letter; but in this respect consultants and practitioners are in the same boat. And when the general practitioner has given a mere oral direction to a patient to go to hospital and sends no introduction or preliminary information, and yet expresses resentment at receiving no report, I can only mildly expostulate that he expects too much.

Dr. Penny in the present instance exonerates the out-patient department, but complains that he is generally left in absolute ignorance of the treatment received by any of his patients admitted to the wards. As he very clearly points out, a proper co-ordination would be very much to the patient's advantage, would greatly assist his practitioner, and would even (indirectly) profit the consultant. The advantage of a report being automatically transmitted is obvious: the difficulty is to decide who is to be responsible for it. Dr. Penny is advocating no innovation. At one of the hospitals with which I am associated an attempt is being made to introduce such a system. The seniors on the staff treat the scheme and its enthusiasts with good-natured ridicule. They tell us that ever since there was a hospital there have been recrudescences of similar reforms. It is perfectly true, as Dr. Penny says, that only if the hospital consultant is a personal friend can he expect to receive direct information; and not always then, I should say. In the large majority of cases the consultant has no such association or intimate interest, and naturally sees no reason to make inquiries and ensure the transmission of information. Shall the resident be responsible? He will not willingly add the burden of gratuitous correspondence to his multifarious duties. Where there are registrars some automatic arrangement might be in force, and yet so far nothing seems to work. Dr. Penny's picture of the medical history sheet accompanying every patient, as in military practice, seems ideal. But what would happen if the form is lost by the patient? Has even so highly disciplined a nation as the Germans been able to adopt such a universal system of registration and indexing?

Here it is that the general practitioner should help. He should always (not sometimes) display his interest in his patient by writing for information. Dr. Penny may reply that on occasion he has written and received no reply. To this I would answer that it is then his duty to write to the physician or surgeon in charge and complain that he has received no reply. I personally—and I trust I speak for all my colleagues in similar position—would never hesitate most strictly to reprimand a resident in his omission to perform what is a fundamental obligation.

Does it not seem that making rules and regulations is less likely to produce the desired result than a determination for all concerned privately to undertake what is only to be expected among colleagues?—I am, etc.,

September 21st. A CONSULTING PHYSICIAN.

TONSIL AND ADENOID OPERATIONS IN HOSPITAL PRACTICE.

SIR,—Nothing in surgery or medicine permits of one dogmatic opinion. Your correspondents, if they are permitted by the hospital authorities to exercise their judgement—and, what is of more value, put it into effect at hospital—can conscientiously in one case send a child home on the same day of operation and in another case insist on admission to the wards.

In private practice all throat surgeons perform the majority of tonsil operations on children at the child's home. Under the following conditions I consider it a safe and reasonable procedure for children to be sent home on the same day.

1. If the child's home is suitable. This the lady almoner department can easily report on previously.

2. If, in addition, a suitable conveyance is supplied. A hospital ambulance should be at the disposal of these cases. I have witnessed parents bundling their child, fresh from operation that day at the hospital, into a crowded tramcar to take them home. It is revolting circumstances of this nature that drive critics to the extreme of "admit all cases of tonsil operations." A small provision of this nature in the way of adequate ambulance accommodation would go far to remove this blot on hospital administration.

3. Never perform tonsil operations on children as out-patients in inclement weather. I have on many occasions —to the disgust of the nursing staff and the children's parents—declined to operate when the weather conditions were unsuitable, and have sent all the patients home. The natural corollary to this, of course, is only to operate on out-patients during the summer. During the last two years I had the privilege of assisting Mr. E. A. Peters and Mr. Wharry at the Bolingbroke Hospital, and can support Mr. Wharry's contention that it does *not* want a large number of cots to cope with a large number of out-patients, providing the operating days are spaced properly.—I am, etc.,

London, W.1, Sept. 21st. N. ASHERSON.

SIR,—The Laryngological Section's resolutions as to precautions in tonsil and adenoid operations were published in the *Proceedings* of the Royal Society of Medicine, Section of Laryngology, for 1921–22 (vol. xv, p. 29)—not 1929, as it appears in my letter in the *Journal* of September 21st (p. 557). I apologize for this error, which is important as showing how many years have passed without those recommendations being uniformly enforced. One particular resolution in point reads thus:

"That all patients requiring operations for tonsils and adenoids should have in-patient institutional treatment, and that a stay of at least forty-eight hours should be insisted on, and a further stay if thought advisable by the medical officer in charge."

The subject was first raised by Mr. Douglas Drew in your issue of November 1st, 1919 (p. 577), and a lengthy correspondence in your columns followed the publication of an article by E. Watson-Williams on "The risks after operation for tonsils and adenoids in outdoor clinics" (*Journal*, December 11th, 1920, p. 887). Furthermore, we had the cordial support of your leading article on "Operations on tonsils and adenoids in outdoor clinics" (January 29th, 1921, p. 167), in which the whole subject was reviewed and the various methods discussed by which the necessary beds could be provided when voluntary hospitals could not find adequate accommodation.

It would appear needful for the Ministry of Health and educational authorities to insist that when children are referred by their medical officers for treatment the various clinics in which their children are submitted to operation should conform to the conditions authoritatively recommended as essential for safety where such operations are to be performed. It seems absurd to blame hospital committees if the medical profession complacently acquiesces in these abuses.—I am, etc.,

Bristol, Sept. 23rd. PATRICK WATSON-WILLIAMS.

SALT DEPLETION BY SWEATING.

SIR,—The correspondence on this subject raises once more the question of medical "fashions." Certainly a few years ago we were told how bad a thing sodium chloride was: in all cases of renal dropsy salt must be cut out of the dietary. Further than that, for the healthy, it was much better to take potassium chloride than sodium chloride, and I remember doctors saying that their salt cellars were now filled with the potash salt. Some years ago I read a paper on "sea water infiltration," and I ascribed the good it did in cases of neurasthenia to the replacement of the *calcium* chloride which, I thought, was low in cases of that complex. I also drew attention to the similarity in composition and proportion between sea water and Ringer's solution. I wrote to the late Professor Bayliss on some points connected with the potassium, sodium, and calcium salts, and he replied (March, 1919): "Sea water, as you say, has a proportion between its salts about the same as Ringer's solution, but it is much more concentrated. . . . There is some evidence that chlorides are essential to the normal functions of the nervous system, and it may be that this is the explanation of the effect of sea water in your cases. If so, it might be useful to give sodium chloride by the mouth in more than the usual quantities." Perhaps it may be that, after all, it is not the metal but the halogen that counts.—I am, etc.,

Bournemouth, Sept. 15th. GEORGE MAHOMED.

X-RAY DEPARTMENT DANGERS.

SIR,—In his letter on September 7th (p. 478) Dr. Bernard Leggett claims to have been the first to use valve-rectified *x*-ray apparatus in private practice "quite eighteen months ago, before any valve *x*-ray apparatus was manufactured in England." I wonder if he is correct in making this claim?

I installed a British-made four-valve transformer in 1926, and have been using it constantly since then. The maker (Schall) was, I think, of opinion that this was the first machine of this type "made in England." I soon discovered that, when using heavy currents with excessive "line drop" due to overloaded mains, one of the valve tubes emitted *x* rays; I admit that it was several months before we discovered the source of these rays and how they were produced.

Dr. Leggett mentions the absence of noise as the only advantage the valve apparatus has over that with mechanical rectification. He surely is forgetting the absence of moving parts, which eliminates attention to bearings and the possibility of the rectifier getting out of phase.—I am, etc.,

Glasgow, Sept. 9th. JAMES R. RIDDELL.

SIR,—It is evident from Dr. Leggett's letter that he has not read Dr. Finzi's article in the July issue of the *British Journal of Radiology*; if he will do so, he will realize that many of his remarks are uncalled for.

Dr. Finzi was one of our early workers; his experience of machines and his knowledge of their physics are probably second to none in this country. He has pointed out a real danger in the use of thermionic valves if the "backing-up" of current from the main is not sufficient to prevent a drop in the filament current when large and sudden draws are made; he also defines the remedy.

Dr. Leggett is quite right when he says that "the mere possession of an *x*-ray apparatus does not constitute a radiologist"; nor does a mere knowledge of physics. A very long experience is also necessary, with a sound knowledge of pathology, medicine, and surgery.—I am, etc.,

Leeds, Sept. 9th. LEO. A. ROWDEN.

REACTIONS FROM SERUM PEPTONE.

SIR,—From time to time medical men write to me to say that my serum peptone preparation, described in the *British Medical Journal* on June 1st (p. 990) in connexion with the treatment of asthma, has produced a reaction in their patients. Sometimes this reaction is considerable. Occasionally, in persons sensitive to peptone, the substance itself produces a reaction. Many medical practitioners think the reaction, even if mild, an unfavourable sign, but with this view I cannot agree. Certainly it is well to avoid a reaction at first, but if after eight to ten injections there is but little improvement, some reaction is desirable (99.5° to 100.5° F.), especially in adult and elderly persons. Several such mild reactions may greatly benefit the patient.

I may here say that it is not necessary to add the minute quantity of agar to the serum. Prepare the serum in this way: add to a four or six ounce glass tube half an ounce of glycerin, and revolve it in the corked tube all along. Then invert the tube and let the glycerin drain out for twenty minutes or so. The glycerin in the tube prevents the blood sticking to its sides in places, as sometimes occurs. Next day pipette off the clear serum into another tube, and add 24 grains of Armour's No. 2 peptone to an ounce. This is not peptone siccum. Shake up and incubate for two or three hours, when the peptone will be dissolved and the mixture clear. It is also alkaline.

Add 10 drops of chloroform to the ounce (4 drops= 1 minim). If a reaction follows the use of this serum peptone it will be much less than that caused by the agar serum; but a reaction may be produced if the peptone or serum peptone is not given sufficiently slowly. Mix 0.5 c.cm. serum peptone with some glycerin and water (4 minims), and inject intravenously very slowly. Increase by 3 minims each time; should a reaction occur too soon do not increase the dose next time. Go up to 2.5 or 3 c.cm. It is advisable always to begin with plain peptone intravenously, and give it a good trial before turning to serum peptone; eight weeks or longer may be required for such a trial. Some cases do all right on peptone, but, in a good many, other methods of treatment must be adopted; they were mostly mentioned in my paper in the *Journal*.—I am, etc.,

London, W.1, Sept. 10th. A. GUNN AULD, M.D.

TREATMENT OF SNAKE BITE.

SIR,—I was interested in the two articles on snake bite in the *Journal* of September 7th (pp. 461 and 470). I have been doing hospital work in India from 1892 until the end of last year, with several furloughs. Before the introduction of the permanganate treatment, besides incision and a continuous hot boric bath, I used hypodermic injections of strychnine, and in cases brought to hospital I had no chance of seeing the snake, which was always described as poisonous—a cobra or karait.

I was called down at 11 o'clock one night to a woman bitten on the thumb and who had only come a very short distance. After incision I injected 20 minims of liq. strychninae and repeated the dose after ten minutes as her pulse was still bad. After another ten minutes I gave a further injection of 10 minims, and thought, as I went up to bed, that if she had not been bitten by a really poisonous snake I might be called down for strychnine poisoning. The next morning, however, I found the woman quite well and happy. Some of the patients were carried in comatose, but every one I had recovered. As soon as antivenene was introduced I gave up the permanganate treatment and adopted that.

I think in many cases the snake may not have been a poisonous one, but the following incident made me cautious. A doctor whom I knew was consulted by a woman who said she had been bitten two hours before by a poisonous snake; as she showed no signs of any disturbance, no treatment was given, but when the doctor returned after visiting an outside case the woman was dead. So even when I was not sure that the snake was poisonous, I treated the patient as if it were, for Indians are quite capable of dying from fright.—I am, etc.,

London, S.E., Sept. 7th. J. M. C. GRAY.

Obituary.

JOHN MALLET PURSER, M.D., D.Sc., F.R.C.P.I.,

Late Regius Professor of Physic, Dublin University.

WE regret to record the death, in his ninetieth year, of Dr. J. M. Purser, formerly Regius Professor of Physic in the University of Dublin, which took place at his residence, Mespil House, Dublin, on September 18th.

John Mallet Purser was the son of Benjamin Purser; he was the brother of Dr. Louis C. Purser, who was vice-provost of Trinity College until his resignation a few years ago, and of Miss Sarah Purser, who is a well-known authority on stained glass in Ireland and on the Continent. At an early age John Purser entered Trinity College and graduated B.A. in 1860. During his Arts course he was a medical student in the Carmichael School of Medicine, which was subsequently absorbed by the Royal College of Surgeons, Ireland. In 1863 he obtained the licence of the Royal College of Surgeons, *and in 1865 he became a licentiate* of the Royal College of Physicians; nine years later he graduated M.D. in the University of Dublin.

In 1869 Dr. Purser was appointed professor of anatomy and physiology in the Carmichael College, and lecturer in ophthalmology in Dr. Steevens' Hospital. After acting for a short time as surgeon to the Royal City of Dublin Hospital he became its physician in 1871, and three years afterwards he was appointed professor of physiology in the medical school of Trinity College; as the result of this appointment he became visiting physician to Sir Patrick Dun's Hospital. Dr. Purser was elected a Fellow of the Royal College of Physicians, Ireland, in 1876, and held office as censor in 1885, and he was for many years an examiner in physiology and histology for the conjoint scheme of the Irish Royal Colleges. As a lecturer in the medical school of Trinity College he was considered to have few equals. It was Purser who first taught pathology in the medical school of Trinity College, and inaugurated a voluntary class in this subject without fees in the medical school. As a physician he acted as the pioneer of the newer therapeutical principles, and was among the few medical men at the time in Dublin who introduced really scientific methods in the treatment of disease. He resigned the professorship of physiology in 1901, and retired into private life. However, owing to the death in 1917 of Professor James Little, the appointment of regius professor in the medical school of Trinity College became vacant, and he was invited by the Board of the College to accept the appointment; this he did, and held the professorial chair until 1925, when he resigned owing to failing health. On his resignation as professor of physiology in 1901 the pupils of his classes decided to commemorate the term of his office; they founded the John Mallet Purser Medal, which is now awarded to the student who gains first place in physiology at the second M.B. examination.

The publications of Professor Purser were few, but his *Manual of Histology and Histological Methods* was much valued during his time; although now out of date and print it is still looked upon as a book of much merit. Apart from his work in the medical school Dr. Purser practised very little, but in difficult cases his opinion as a diagnostician was much sought after by the leading physicians of his time. Some years ago he gave £10,000 to be administered for the benefit of the school of physic and the schools of experimental and natural science in Dublin University. Dr. Purser never married; he travelled a great deal, and took a keen interest in different aspects of music.

CHARLES A. MORTON, O.B.E., F.R.C.S.,

Emeritus Professor of Surgery, University of Bristol; Consulting Surgeon, Bristol General Hospital.

MR. CHARLES ALEXANDER MORTON, whose death, while on holiday in Switzerland, was announced in a recent issue, retired from hospital practice in 1925, after having served for twenty-eight years as professor of surgery at University College, Bristol, and the University of Bristol, for twenty-seven years as surgeon to the Bristol General Hospital, and for twenty-five years as surgeon to the Bristol Children's Hospital. He was also consulting surgeon to the Cossham Memorial Hospital. Nearly the whole of his active professional life was thus closely associated with medical institutions in the city where he was born in 1860. His father, John Morton, was for many years superintending surgeon for the Madras Presidency in the East India Company's service.

From Clifton College Charles Morton went to St. Bartholomew's Hospital, where he had a distinguished student career, winning a Brackenbury medical scholarship and serving later as house-physician. He obtained the M.R.C.S. and L.R.C.P. diplomas in 1881, and later held resident appointments at the Stanley Hospital, Liverpool, the Cumberland Infirmary, the Manchester Children's Hospital at Pendlebury, and the Leicester Infirmary. He became F.R.C.S.Eng. in 1889, and shortly afterwards returned to Bristol, and on his appointment as surgical registrar began his long connexion with the General Hospital. In 1893 he was appointed assistant surgeon to that hospital, and four years later was elected to the professorship of surgery at University College, Bristol. The thoroughness and attention to detail for which Morton was noted as an operating surgeon were equally conspicuous in his work as a teacher in the wards and lecture theatre. For a large part of the war he served with the rank of major, R.A.M.C.(T.F.), as

surgeon to the Beaufort War Hospital, and in recognition of this work was created O.B.E. (military) in December, 1919. During his years of active practice Morton contributed many papers on surgical subjects to the *Lancet*, to the *Bristol Medico-Chirurgical Journal*, and to our own pages.

Morton's interest in hospital work and the problems of hospital administration did not cease when he relinquished his duties as hospital surgeon and teacher. He became a member of the Bristol Board of Guardians, and, as our correspondence columns have lately testified, he applied his mind with characteristic energy to the new situation which will arise under the Local Government Act of 1929, when Poor Law functions are transferred to county councils and county borough councils. In particular, he advocated the setting up of a special committee for each area to deal with all forms of the treatment of disease, and he was strongly of the opinion that, in order to bring the transferred Poor Law hospitals up to the standard of the voluntary hospitals, the relationship of the patients to a staff of specialists must be the same in those institutions as in the voluntary hospitals.

EDWARD PETRONELL MANBY, M.D., D.P.H.,

Medical Officer to the Ministry of Health.

WE regret to record the death of Dr. E. P. Manby, on September 20th, at his residence in Kensington.

Edward Petronell Manby was born in 1864, and received his medical education at Cambridge and Guy's Hospital. He obtained the diploma M.R.C.S. in 1886, and in the following year graduated M.B., B.Ch.Camb. He proceeded M.D. in 1891, and became D.P.H.Camb. three years subsequently. Among the appointments he held were those of resident medical officer to the Fountain Fever Hospital of the Metropolitan Asylums Board, assistant medical officer of health to the city of Liverpool, examiner in public health in the Universities of London, Liverpool, and Leeds, and, finally, medical officer at the Ministry of Health. For some years Dr. Manby was a member of the British Medical Association, and was honorary secretary of the Section of State Medicine at the Annual Meeting held at Ipswich in 1900. He was also a member of the Middle Temple.

We are indebted to Dr. F. N. KAY MENZIES, medical officer of health and school medical officer, London County Council, for the following appreciation:

The sudden death of Dr. E. P. Manby is an irreparable loss to the Poor Law medical service, especially of London. It is made doubly so by the fact that his old friend and colleague Dr. Meredith Richards was compelled to resign his position at the Ministry of Health in the spring of this year owing to serious illness. Manby and Meredith Richards knew more about Poor Law medical work than almost any other medical man in existence, and therefore the fact that they have both been lost to the service within the last few months is nothing less than a national misfortune, more especially in view of the coming into operation on April 1st next of the Local Government Act, 1929. At a time like this their wide and matured experience, wise discretion, and sound judgement would have been of incalculable assistance to all those medical officers of health who will shortly be called upon to undertake great and onerous responsibilities in connexion with the transfer of the Poor Law medical work to public health authorities. It would be quite impossible for me to give adequate expression to the deep debt of gratitude which I, personally, and, I am confident also, all the medical superintendents of the Poor Law infirmaries of London, feel was due from every one of us to Manby. It was my great good fortune to spend many weeks during the first six months of this year in visiting with him all such infirmaries and Poor Law institutions in London. His knowledge and experience of Poor Law medical problems in the metropolis was both profound and intimate, based as it was upon many years of close study and active work in connexion therewith. It is easy, therefore, for anyone to appreciate what an enormous help he was to me personally during these visits, and in the many conferences we had together. He was held in the highest possible esteem by all the medical superintendents of the London infirmaries, by whom his loss will be very deeply and sincerely regretted. His duties were often of a most difficult and trying nature, requiring immense tact, patience, and wisdom; everyone who knew him will agree that he exhibited these qualities to a superlative degree in all his work. He was always easily accessible, always ready to help, and could always be counted upon to give of his best in any direction which might be helpful to his colleagues. His loss, therefore, at this time of all times is a real disaster to everyone concerned with the Poor Law medical service, especially of London. The heartfelt sympathy of all his friends and colleagues will go out to Mrs. Manby and their only child, Jack, now at Westminster School.

We regret to record the death, in his eighty-fourth year, of Dr. W. R. SPEIRS, which took place on September 5th at his home in Ainsdale, near Southport. William Robert Speirs received his medical education at the University of Glasgow, where he graduated M.B. (with commendation) in 1867 and C.M. in 1870. In the old Royal Infirmary he served under Lister, and was his prizeman in clinical surgery. After occupying for some time posts as ship surgeon, Dr. Speirs settled in Haltwhistle, Northumberland, in which district he practised for over forty years. He was the first medical officer of health for the Haltwhistle Rural District Council, and held appointments as medical officer to the Gilsland Convalescent Home and as honorary medical officer to the Plenmellor Industrial School. He was an active worker on behalf of the St. John Ambulance Association. On his retirement he went to live in Ainsdale, where he soon identified himself with local affairs, becoming a member of the town council, a position which he occupied for thirteen years. So deeply were his services appreciated that he was offered the office of mayor of Southport, but owing to his advanced age he had to decline the honour. He is survived by three sons and four daughters.

We regret to record the death, at the early age of 32, of Dr. JOSEPH WOOD BALNAVES, which took place in Aberdeen on September 11th. He received his medical education at the University of Aberdeen, where he graduated M.B., Ch.B. in 1923. He held an appointment as honorary physician to the Tarporley and District War Memorial Hospital, and was a member of the British Medical Association and of the Chester County Panel. We have received the following appreciation from Dr. T. W. E. Moreton, with whom he was in general practice in Cheshire. "Joe" Balnaves, as everyone called him, was brought up in Aberdeen, but was a living contradiction of the alleged hardness of her sons. Generous in his life, he met death bravely after a happy and all too brief career. His athletic prowess was shown early at Aberdeen University, where in 1920 he gained a full "blue." During the war he held a commission in the Gordon Highlanders, and was wounded in France in 1916. A severe shrapnel wound of the leg kept him disabled till 1918. Twice he was on the operating table to have his leg amputated, but each time he was sent back in the hope that the limb might be saved. This hope was mercifully realized, and Balnaves, though dreadfully pulled down by septicaemia, was able to resume his studies at the university. He had a finely developed artistic sense, and in his small but growing library could be found the latest good work in prose and poetry; he was also an excellent amateur actor. Two years ago he married Miss Marion Macdonald Symons, who nursed him constantly since his final breakdown two months ago. An operation for carcinoma of the stomach, from which he recovered with marvellous rapidity, indicated, however, that his life was destined to be a short one. Going for his holidays at the beginning of July, he drove his car himself from Cheshire to Aberdeen, but a few days later he showed symptoms of a serious nature which developed in spite of all treatment, medical and surgical. Three years of pleasant association with him in partnership at Tarporley taught me something of his sterling qualities. What his future might have been none

can tell, but he had made his mark among his patients and friends. He was laid to rest at Allenvale Cemetery, Aberdeen, but we, his friends, will remember that, as William Penn wrote: "Tho' death be a dark passage, it leads to immortality, and that's recompense enough for the suffering of it."

We regret to record the death, in his eighty-first year, of Dr. LEWIS MARSHALL, which took place on September 12th at Cheltenham. Dr. Marshall received his medical education at Bristol and Aberdeen, qualifying M.R.C.S.Eng. in 1870 and L.S.A. in 1872; in 1871 he graduated M.B., C.M.Aberd. with honours, proceeding M.D. in 1874. Shortly after his graduation he proceeded to Nottingham, where he held an appointment as house-surgeon to the General Hospital; later he engaged in private practice as specialist in diseases of children, and in 1877 he was appointed honorary physician to the Nottingham Children's Hospital. In 1909 he became consulting physician to the hospital, and occupied this position till his retirement from practice about seven years ago. Lewis Marshall was an active member of the British Medical Association; in the course of his professional career he was president of the Midland Branch, and when the Association held its Annual Meeting at Nottingham in 1892 he was president of the Section of Diseases of Children. He had also held the position of president of the Nottingham Medico-Chirurgical Society. He is survived by a widow, one son, and two daughters.

We regret to record the death, in his fiftieth year, of Mr. ROBERT TOWNLEY SLINGER, which took place on September 10th. Robert Townley Slinger was born in Manchester, and received his medical education at Owens College. In 1903 he graduated M.B., Ch.B.Viet. with honours, and then held in turn appointments as senior resident medical officer to the Manchester Children's Hospital at Pendlebury, and house-surgeon and accident house-surgeon to the Royal Infirmary, Manchester. With the late Sir Victor Horsley he conducted an investigation of orientation in points of space by the muscular, arthrodial, and tactile senses of the upper limbs; a joint paper recording the results of this work appeared in *Brain* in 1906. In 1908 Slinger became a Fellow of the Royal College of Surgeons of England, and a year later he joined the late Mr. T. P. Gostling in partnership at Worcester. He was appointed honorary anaesthetist and surgical pathologist to the Worcester General Infirmary in 1910. During the great war he served in France as surgical specialist, but owing to the ill health of his partner he had to resign his commission in 1917 and return to civilian practice. In 1918 he was appointed honorary surgeon to the Worcester General Infirmary. Robert Slinger was a keen member of the British Medical Association, and for some time was a member of the Executive Committee of the Worcester Branch. He was a Freemason. One of his colleagues sends the following appreciation: The death of Mr. Slinger at the early age of 49, when he might have been expected to use his exceptional skill for many years longer, has left his professional brethren, his patients, and his many friends with a feeling of deep sorrow and an acute sense of personal loss. This loss is so great, not only on account of his ability as a surgeon, but of his personal charm and his high standard of honour, which he always maintained in his relations with his fellow practitioners. During his twenty years of practice at Worcester he had shown himself untiring in his efforts to relieve the sufferings of all classes of the community. He was a man whom everybody appreciated and many loved; a great number of his patients were his personal friends, to whom he was of unfailing help in all their troubles. Slinger was ever ready to help a sick colleague, not only in treating his ailment, but in looking after his patients. Seven years ago, and again five years ago, he had serious illnesses, which undoubtedly lowered his resistance to infection. It was the heavy work entailed by the influenza epidemic of last spring which caused his last illness and his death; for although he was far from well, his sense of duty made him work until he broke down. He is deeply mourned and sincerely missed by all who knew him.

The following well-known foreign medical men have recently died: Dr. EDOUARD LONG, professor of neurology at Genéva; Professor ARNDT, director of the University Skin Clinic of Berlin, aged 55; Professor C. O. GÜNTHER of Berlin, an authority on public health, aged 74; Dr. EUGÈNE DEVEZ of Mons, president of the International Association against Tuberculosis and of the National Belgian League for Combating Tuberculosis; Dr. SAMUEL WALTER KELLY, professor of children's diseases at the Cleveland College of Physicians and Surgeons from 1893 to 1910, and author of *Surgical Diseases of Children*, of which the third edition has just been published; and Dr. JARKOWSKI, an eminent neurologist of Warsaw.

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THE session 1929-30 opens on Monday, October 7th. Students of the Faculty of Medical Sciences will be received by the Provost and Dean on that day as follows: First-year students, between 10 a.m. and 1 p.m.; students of later years between 2.15 and 4 p.m.

Public lectures that have been arranged for the first term include the Rickman Godlee Memorial Lecture, by Viscount Grey of Fallodon, on November 7th, at 5.30 p.m.; "Medicine in the days of Shakespeare," by Dr. Herbert Spencer, on November 25th, at 2 p.m.; four lectures on "Secretion of the digestive juices," by Dr. R. J. Brocklehurst, on October 14th, 21st, and 28th, and November 4th at 5 p.m.; and three lectures on "Chemical forces an[illegible] Professor K. Fajans of the University of [illegible] and 18th, at 5.30 p.m. Particulars of [illegible] may be had on application to the secretary, University College, London, W.C.1. A stamped addressed envelope should be enclosed.

The following elections in the Faculty of Medical Sciences of the College have been made: Buckuill Scholarship (160 guineas), K. C. Eden; First Exhibition (55 guineas), A. G. Hounslow; Bursary (£25 a year for two years), I. Doulach; Epsom Scholarships, C. C. H. Harvey and D. Joy.

[illegible]ised

[illegible]OSTIC. GUY'S HOSPITAL MEDICAL SCHOOL.

[illegible]his [illegible]g awards have been made:

THE following Scholarship (£100).—H. A. Treble.

War Memorial Scholarship (£80).—Divided between C. A. Clarke and S. M. Silverstone.

Open Senior Science [illegible]

[illegible] OF SURGEONS OF ENGLAND.

ROYAL COLLEGE OF S[illegible]strations.

Museum Demonstrations.—[illegible] specimens in the Museum [illegible]ge, Lincoln's Inn Fields, will be given in the theatre of the College by Sir Arthur Keith [illegible] W.C., at 5 p.m. on Fridays and Mondays, [illegible] ient and modern, on demonstrate specimens of trephining, ancestral, congenital and [illegible]ilities in the sacro-October 18th; dislocations of the hip-joint [illegible], Wakeley will acquired, on October 25th; and spinal deform[illegible]re the brain on [illegible] region, on November 1st. Mr. Cecil P. G[illegible] November 4th, demonstrate specimens illustrating tumours of [illegible] practitioners, October 21st, calculi on October 28th, and cysts on N[illegible]s.

The course is open to advanced students and medical p[illegible]

The Services.

ROYAL ARMY MEDICAL CORPS.

MAJOR-GENERAL SIR ALFRED P. BLENKINSOP, K.C.B., C.M.G. [illegible] has been appointed Colonel Commandant, Royal Army Medical Corps, in succession to Major-General Sir M. W. O'Keeffe, K.C.M.G., C.B.

DEATHS IN THE SERVICES

Lieut.-Colonel John Robert Mallins, O.B.E., J.P., R.A.M.C. (ret.), died in Queen Alexandra's Military Hospital, Millbank, on July 23rd, aged 69. He was born on July 6th, 1860, and educated at Trinity College, Dublin, where he graduated as B.A. in 1882, and subsequently as M.B. in 1895. Entering the army as surgeon on August 2nd, 1884, he became lieutenant-colonel after twenty years' service, and retired on December 14th, 1904. After retirement he was employed as medical officer of the Military Prison, Gosport, from 1906 to 1908. He served in the Sudan campaign of 1885-86 in the Egyptian Frontier Field Force, receiving the medal and the Khedive's bronze star; and in the South African war from 1899 to 1902, when he took part in the battle of Colenso, the relief of Ladysmith, and the action of Spion Kop, also in operations in Natal and in the Transvaal, was twice mentioned in dispatches—in the *London Gazette* of February 8th, 1901, and July 29th, 1902—and received the Queen's medal with three clasps and the King's medal with two clasps. He rejoined for service in the recent war of 1914-18, from August 8th, 1914, when he received the O.B.E.

Medical News.

AT the opening of the winter session of Guy's Hospital Medical School on October 1st, at 3 p.m., Sir Humphry Rolleston, Bt., will distribute the prizes and address the first meeting of the Physical Society on "Medical societies as an educational factor."

THE formal opening of the new session of the Birmingham University Faculty of Medicine will take place in the Medical Theatre on Tuesday, October 1st, at 4.30 p.m. Prizes will be presented to successful students by Sir E. Farquhar Buzzard, Bt., who will afterwards give an address on "Arrogance and ignorance in medicine."

AT the opening of the winter session of the University of Durham College of Medicine on Friday, October 11th, the Duke of Northumberland, Chancellor of the University, will deliver an address on some scientific theories and their foundations, at 4.15 p.m. A joint dinner with the University of Durham Medical Graduates' Association will be held on the same evening at the Central Station Hotel, Newcastle, at 7.30, when the Chancellor will be the guest; price of tickets 12s. 6d., exclusive of wine.

DR. F. N. KAY MENZIES, Medical Officer of Health, London County Council, will deliver the inaugural address at the opening of the winter session of Westminster Hospital Medical School on Tuesday, October 1st, at 3 p.m. The annual dinner will be held in the evening at 7.30, at Grosvenor House, Park Lane, W.1; Mr. Stanley Dodd, F.R.C.S., will be in the chair.

THE annual dinner of the Charing Cross Hospital Medical School will be held at Gatti's Restaurant, Strand, on Saturday, October 5th, at 7.30 p.m.; the chair will be taken by Dr. J. M. H. MacLeod. The prize distribution will take place at the hospital at 4.30 p.m. on the same day.

THE annual dinner of past and present students of University College Hospital will take place at the Hotel Cecil on Friday, October 25th, at 7.30 p.m., under the chairmanship of Dr. E. A. Barton.

THE seventeenth annual meeting of the National Association of Insurance Committees will be held at the Hearts of Oak Buildings, Euston Road, London, N.W., on October 3rd, 4th, and 5th. The agenda paper includes motions by the County of Worcester in regard to appeals to the Minister of Health under Medical Benefit Regulation No. 38; by Cheshire in regard to investigation of excessive prescribing and the administration of maternity services; and by Durham urging that insurance practitioners should be authorized to order or supply such trusses and other supports as they may consider necessary for insured persons. On the morning of Saturday, October 5th, addresses will be given by Dr. John Hall on "Health education" and by Sir William E. Hart on "Recent legislation affecting public health."

A SPECIAL meeting of representatives of the Middlesex, Kent, Essex, Hertford, and Surrey County Councils, convened by the Essex County Council, is being held this week in the Middlesex Guildhall, Westminster, to consider the problem of the dumping of London refuse. The extent of the problem and the inadequacy of the present methods of dealing with it were graphically indicated by Mr. J. C. Dawes in his *Report of an Investigation into the Public Cleansing Service in the Administrative County of London*, to which we drew attention in a leading article in our issue of April 20th (p. 734).

THE annual general meeting of the Smoke Abatement League of Great Britain will be held on October 4th at the Palace Hotel, Buxton, and on the following day a joint meeting will be held with the Coal Smoke Abatement Society for the purpose of inaugurating a new body to be formed by amalgamation of the Society and the League. Hitherto the former has worked chiefly in London, while the latter has confined its attention mainly to the provinces. It is believed that fusion of the two organizations will greatly strengthen the growing movement against smoke. The central offices of the new body will be in Manchester, and there will also be offices in London and Glasgow. One of its first steps will be the publication of a periodical entitled *Clean Air*, of which the first number will be issued in November at the time of the Smoke Abatement Exhibition in Manchester. All inquiries regarding the conference should be addressed to the Secretary of the Smoke Abatement League of Great Britain, 23, King Street, Manchester.

THE opening meeting of the new session of the St. Pancras Division of the British Medical Association will be held at B.M.A. House, Tavistock Square, W.C.1, on Tuesday, October 1st, at 9 p.m., when Dr. Eric Pritchard will give an address on infant feeding. In view of the importance of the subject to nurses, invitations have been extended to them to be present on the occasion. As will be seen from the list printed in the *Supplement* this week, an interesting programme has been arranged by the Division for the forthcoming session.

THE eighty-eighth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain will open on Wednesday next, October 2nd, at 3 o'clock, when the Hanbury Gold Medal will be presented to Professor Henry Hurd Rusby, M.D., of New York, who will afterwards give the inaugural sessional address.

THE Fellowship of Medicine announces that an all-day course in gastro-enterology will be held at the Prince of Wales's General Hospital, Tottenham, N.15, from September 30th to October 4th. During October several special courses will be held: an all-day course in cardiology at the National Hospital for Diseases of the Heart, October 7th to 19th (strictly limited to twenty entries); an afternoon course in ophthalmology at the Central London Ophthalmic Hospital, October 7th to November 2nd; a course in tropical medicine at the London School of Tropical Medicine on Tuesday and Thursday afternoons from October 8th to 31st; gynaecology at the Chelsea Hospital for Women, October 14th to 25th; diseases of children at Great Ormond Street Hospital, October 14th to 26th, mornings only; a whole-day course in diseases of the throat, nose and ear at the Central London Throat, Nose and Ear Hospital, October 14th to November 2nd, comprising clinical, practical operative, and pathological classes; an intensive course in medicine, surgery, and the specialties at the Metropolitan Hospital from October 21st to November 2nd; and an M.R.C.P. evening course of lectures on Tuesdays and Fridays at 8.30 p.m., from October 15th to December 6th, at the Medical Society of London, 11, Chandos Street, W.1. Copies of all syllabuses and information regarding the general course of work at the associated hospitals can be obtained from the Secretary of the Fellowship, 1, Wimpole Street, London, W.1.

A THREE days' post-graduate course has been arranged at St. Mary's Hospital, Paddington, commencing on Friday, October 4th, at 11 a.m., when Professor F. S. Langmead will lecture on Graves's disease; at noon Dr. T. C. Hunt will deal with recent aids in diagnosis of some common diseases; Dr. Aleck W. Bourne will give a lantern lecture at 2.15 p.m. on the action of certain drugs on the uterus in labour; and at 3.15 p.m. Dr. A. Hope Gosse will give a lantern demonstration concerning diseases of the chest. On Saturday, October 5th, Mr. Duncan C. L. Fitzwilliams will lecture at 10 a.m. on the treatment of malignant disease by radium, with epidiascopic illustrations; at 11 a.m. Sir William Willcox will discuss catarrhal jaundice; at noon Robert Hutchison will give an account of the common dyspepsias of childhood; at 2.15 p.m. Dr. T. G. Stevens will speak on the retention of urine in women; and at 3.15 p.m. Dr. Albert Eidinow will describe clinical methods in light treatment. On Sunday, October 6th, at 10.15 a.m., Mr. R. M. Handfield-Jones will discuss the pitfalls in urological diagnosis; at 11 a.m. Dr. C. M. Wilson will lecture on diabetes; and at noon Mr. V. Zachary Cope will discuss abdominal pain. The meetings will be held in the library of the Medical School, with the exception of the lantern lectures, which will take place in the physiology theatre; they are open to all medical practitioners without fee.

UNDER the auspices of the North Kensington Women's Welfare Centre a conference of doctors in charge of birth control clinics was held on July 10th, for the purpose of interchanging annual reports and discussing various problems relating to the work of the clinics. The following resolution was carried unanimously: "This conference of medical men and women and of the medical officers of birth control clinics throughout the country considers that a regular examination with speculum is an essential before recommendation of a conception-control method; and urges the committees of such clinics to afford facilities to their medical officers to make this examination." At present such examination is carried out systematically at the North Kensington Women's Welfare Centre and, in certain cases, at most other clinics.

THE committee appointed by the Minister of Pensions to inquire into the administration of the Queen Alexandra Hospital, Cosham, Hampshire, held their second meeting on September 16th and afterwards inspected the hospital. They desire it to be known that they are willing to consider any statements relating to the administration of the hospital from patients, ex-patients, or others, and communications should be addressed to the secretary of the committee, Mr. R. Herbert, at 18, Great Smith Street, London, S.W.1.

THE Council of the Royal Institute of Public Health on September 19th completed the purchase of a vacant freehold island site on the north side of Queen Square, Holborn, W.C.1, for the purpose of erecting thereon the new premises of the Institute.

THE first congress of the Latin Society of Oto-rhino-laryngology will be held at Madrid on October 7th, under the presidency of Professor Tapia.

SEPTEMBER 2nd was the centenary of the birth of the celebrated Munich surgeon Johann Nepomuk von Nussbaum (1829–1890), who contributed largely to the introduction of Lister's antiseptic methods into Germany.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861,-9862, 9863*, and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

ABDOMINAL SURGERY AT SEA.

"T. S. S.," a [illegible] to hear of the best book or [illegible] ould suit him in any emerge[illegible] igh seas. The first port of [illegible] there are very few ships [illegible] to relieve his mind somewhat he would like to have such a treatise by him.

PROLAPSE CAUSED BY DYSCHEZIA AFTER LABOUR.

DR. J. R. BAKER (Scunthorpe, Lincs) writes: I have recently had a case which has raised in my mind the question of dyschezia after labour being a common cause, if not the commonest, of rectocele and cystocele. This woman told me that on one occasion, four days after labour, she had great difficulty in defaecating, and that she strained for a full half-hour in her determination to get a passage. She said that she was certain that the discomfort and symptoms of a cystocele, which have had to be relieved by a ring, date from that half-hour of prolonged bearing down. If this is common, what is the best remedy? Instruction to refrain from so doing is the first, but the alternative is not always simple. What is the best aperient for use immediately after labour? The almost universal castor oil seems to me to be physiologically unsound and unnecessary, while liquid cascara sagrada and liquid paraffin are not always effective.

INCOME TAX.

Purchase of Instruments and Books.

"A. W. M. D." has been informed by the inspector of taxes that cost of purchasing instruments and books cannot be allowed unless incurred by way of replacement. But some of the income tax books which he has consulted appear to treat all purchases as allowable expenses.

*** The question is primarily governed by statute. The rules applying to Schedule D, as laid down in the Income Tax Act of 1918, prohibit the deduction of "any sum employed . . . as capital in such . . . profession," and it is undeniable that the cost of the original equipment or of improving, as distinct from maintaining, that equipment is an outlay of capital. The authorities which "A. W. M. D." has consulted have apparently assumed that this fundamental principle is understood, and the expenditure on instruments to which they refer must be that incurred in renewals and repairs. Presumably—though the question is not free from doubt—periodicals and books purchased merely to keep a practitioner's medical library up to date would be allowed; the point has not been contested in the courts, though in the case of Daphne v. Shaw, heard in 1926, a depreciation allowance was refused for a professional library.

Visitor to the United Kingdom.

"Cocoa" resides abroad and has no residence in the United Kingdom. He inquires as to his position if he visits this country for twelve months—five in one financial year and seven in the next. He derives no income from sources within the United Kingdom.

*** He will not be liable to income tax in respect of the year in which he spends less than six months in this country, but in respect of the second year he will be liable to account for tax on the amount of income received by him in that year. There is no six months' allowance in the second year, but he will be entitled to the usual "personal allowances."

LETTERS, NOTES, ETC.

TONSILLECTOMY AND OLD AGE.

MR. E. C. [illegible] F.R.C.S.Ed. [illegible] writes: At the British Medi[illegible]r, when Dr. F. C. Eve was [illegible]paratus, he mentioned old a[illegible] time ago I was called out to an old lady, 76 years of age, who was running an evening temperature with a fast pulse. [illegible] clinical evidence had shown this to be du[illegible]nder gas and oxygen anaesthesia we [illegible] the [illegible]ethod. She made an uninterrupted [illegible] up out of bed in three days. Whilst [illegible] hat operation is not feasible in every case of septic tonsils in old people, yet this case illustrates that age in itself is not necessarily a contraindication to tonsillectomy. By a coincidence I removed her great-grandson's tonsils and adenoids on the same day.

THE PHENOL CONTENT OF LYSOL.

THE products marketed as lysol and lysol solution differ so much in their phenol content that error is likely to arise if medical practitioners ordering them fail to specify exactly which they intend their patients to use. Only registered pharmacists are entitled to sell lysol, which, according to a decision given by Mr. Graham Campbell at Bow Street police court in 1925, must be standardized to contain approximately 50 per cent. of phenols. On the other hand, the product sold in some retail shops as lysol solution may contain no more than 3 per cent. of phenol and its homologues.

THE ART OF PRESCRIBING.

DR. F. L. SPALDING (Worcester), in the course of a letter, writes: Your timely leader on "The decline of the art of prescribing" will be greatly appreciated by general practitioners who are actively engaged in the treatment of minor maladies and diseases in the early stages, and who are really specialists in this department of the practice of medicine. Men who assert that drugs are of no use, and that the art of prescribing is useless, can never have intelligently studied the matter, probably through lack of requisite knowledge. This aspect of medicine is not adequately dealt with in medical schools to-day. Drugs, I believe, are of the utmost value in the treatment of the early phases of disease, apart from the relief of symptoms, which is so important to the patient. Your leader is of particular value, as it serves to emphasize the danger to which panel patients are subjected by the short-sighted policy of the Ministry of Health, which, by inflicting fines for so-called "excessive prescribing" (which often means that not enough stock mixtures have been prescribed), tends to encourage slackness in this matter.

TREATMENT OF THREADWORMS.

DR. GARRY SIMPSON (London) writes: I have found bismuth carbonate, as suggested by Loeper, a specific. For an adult three doses of 20 grains, at intervals of four hours, and for a child under 7 years of age 10 to 40 grains per dose. The treatment is simple and cure instantaneous.

DIAGNOSIS OF EYE CONDITIONS.

Corrigendum.

DR. G. W. KENDALL asks us to state that the drawings shown by him in illustration of his presidential address on this subject to the City Division of the Metropolitan Counties Branch (*Supplement*, September 14th, p. 141) were kindly lent by Professor Eyre. We take this opportunity of correcting a slip. Line 7, column 2, of our abstract should read *Hypopyon ulcer*, etc., the term *hypopyon* applying here to the sterile exudation found in the anterior chamber in association with corneal ulceration.

EPSOM COLLEGE: SALOMONS ENTRANCE SCHOLARSHIP.

AN error occurred in the notice of this scholarship on September 21st (page 564): the sentence should have read "candidates must have been over the age of 11 and under 14 on January 1st last." It is now announced that applications must reach the secretary of Epsom College (49, Bedford Square, W.C.1) by the morning of Tuesday, October 1st.

A WARNING.

MR. C. [illegible] to warn our readers against canv[illegible] printing. One in particular (he s[illegible] an [illegible] victims, and on no account should [illegible] of any goods ordered; most of my [illegible] "rooked" in sums up to £1 by one gentleman who tells a most plausible tale.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 52, 53, and 54 of our advertisement [illegible]rtnerships, assistantships, [illegible]

A short summ[illegible]rtisement columns appears in the *Supplement* at page *155*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

262. The Causes of Resistance to Insulin Treatment.
H. F. ROOT (*New England Journ. Med.*, August 1st, 1929, p. 201) reports a case of haemochromatosis in which gradually increasing daily doses of insulin up to 1,680 units in twenty-four hours failed to prevent death in coma. The condition was due to progressive loss of function of the islands of Langerhans; the necropsy revealed destruction of cells in the liver, heart, and elsewhere, but it was most marked in the pancreas in which very little actual pancreatic tissue remained. Although great variations are sometimes observed in the amount of insulin required to reduce hyperglycaemia, so that the term "insulin resistance" seems justified, no instance of true uncomplicated diabetes in which insulin failed to reduce the sugar of the blood or urine has yet been noted. The cases so far observed showing relative resistance to insulin treatment may be classified in respect of the various originating causes as follows: (1) those due to destructive processes in the pancreas causing great limitation of the insulin-producing tissue, as in cancer, haemochromatosis, and acute pancreatitis; (2) those in which complicating diseases of other endocrine glands, notably the thyroid, the pituitary, or the adrenals, or acute infections stimulating such glands to overactivity, exist; (3) those due to complicating disturbance of the liver function, as in cirrhosis, chronic congestion, and syphilis; and (4) those due to disturbances of the function of the skin and muscles either from disease, poor development, or lack of tone. The probable existence in normal muscle of an enzyme which reacts with glucose only in the presence of insulin has been suggested.

263. Ketonuria in Relation to Health.
H. F. HÖST and V. BÜLOW-HANSEN, jun. (*Acta Med. Scand.*, July 2nd, 1929, p. 325), comment on the many divergent opinions regarding the relation of diet to ketonuria. Several authorities deny the possibility of calculating the degree of ketonuria resulting from changes in the composition of the diet. It is generally recognized that ketone bodies may be found in the urine of healthy persons on ordinary diet. The authors determined the degree of ketonuria in twelve diabetic patients on various diets, and also the percentage of ketones in twenty specimens of the total daily urine of fifteen non-diabetic patients taking ordinary diet, in order to ascertain the maximal normal ketonuria. They found appreciable quantities of ketones in almost all the specimens from healthy persons: the daily maximum being 0.3 to 0.4 gram. It is probable that a great increase of ketones in the blood is the main cause of diabetic coma, but it is not known whether a small persistent increase is also injurious. Neither insulin administration nor hyperglycaemia had any direct influence on ketonuria, but an acute febrile infection (angina) caused a great increase in the quantity of ketones. Eight diabetic patients were discharged with more or less increase of ketones (from 0.5 to 3 grams per diem). One was lost sight of; in two other cases the diabetes became worse. One discontinued his special diet; the other apparently did not. After two years the remaining five patients do not show any symptoms of aggravation of diabetes. This is considered by the authors to support the opinion that a small increase in ketonuria is not injurious.

264. Low Basal Metabolism following Thyrotoxicosis.
W. O. THOMPSON and PHEBE K. THOMPSON (*Amer. Journ. of Surg.*, July, 1929, p. 48) have made a study of 66 cases which showed a basal metabolic rate below *minus* 15 per cent. after treatment (surgical, *x*-ray, or iodine alone) for toxic goitre. Only 11 of these patients had signs and symptoms of myxoedema; in 3 the myxoedema was temporary and in 8 presumably permanent. It is considered significant that in one of the temporary cases the myxoedema was shown to be the result of the post-operative administration of iodine. Of the remaining 55 non-myxoedema patients, in 26 the low metabolism was temporary and in 21 permanent; in 8 the type could not be determined. It is shown that the temporary depressions of metabolism, unassociated with myxoedema, were probably due to two causes: a temporary thyroid deficiency, which, because of its short duration, was not detectable clinically; and a transient return to the normal metabolic level of the individual. Permanent low metabolism without myxoedema following thyrotoxicosis appeared in most instances to represent a return to a normal metabolic level, which was probably low even before the development of the disease. The interpretation of the degree of basal metabolic elevation is, therefore, directly affected by the level of the patient's normal metabolism. In most of the patients with myxoedema the basal metabolic rate was below *minus* 25 per cent. In all the patients whose low metabolism could be regarded as normal, the rate was above this figure.

265. The Tuberculin Reaction in Elderly Patients.
A. MÜLLER-DEHAM and HELENE JOKL (*Wien. Arch. f. Inn. Med.*, June 10th, 1929, p. 519) point out how senility affects the reaction to disease. Infections which normally produce violent inflammation, pain, and high temperature are often attended in elderly patients with none of these defence mechanisms. The authors thought that the case would be similar with the results of tuberculin tests, but they found that the reverse occurred. Of 300 patients, mostly over the age of 60, and excluding those who probably had tuberculosis, only 6 per cent. failed to react to Pirquet's test, and the local reactions were exceptionally strong. It was thought that the explanation might be that the senile skin reacted to all irritants more violently, but it was found that intracutaneous injections of saline, morphine, and adrenaline showed no marked differences in respect of the reactions which followed in young and old patients. The authors add that the phenomenon of increased sensitivity to tuberculin in the aged is not confined to the skin, but is a property of the whole organism. Thus in 88 senile patients the percentage who gave a general reaction, and also the intensity of this reaction (increased temperature and respiratory rate), were noticeably greater than in people taken at random.

266. Molluscum Contagiosum in Turkish Baths.
C. G. CROWLEY (*Med. Journ. Australia*, June 15th, 1929, p. 806), who records three illustrative cases, states that Malcolm Morris, Crocker, and Hutchinson drew attention to the association of Turkish baths and molluscum contagiosum in England. Molluscum contagiosum is very rarely encountered in Australia, so that the incidence of three cases in two days recently seen by Crowley at Melbourne is very unusual. In each case the patient had attended the same Turkish bath a week or so before the eruption appeared. The proprietor of the baths was accordingly warned of the necessity of boiling towels, mats, and similar material, and of treating the slabs with steam and disinfectant.

Surgery.

267. A Modified Abdominal Incision.
J. T. MASON (*Arch. of Surg.*, July, 1929, p. 129) describes an abdominal incision which gives greater exposure than any other, and is easy of closure. It is a combination of a longitudinal and a transverse incision, and allows the tension on the scar line to fall on both of the recti muscles instead of on one, the strain of abdominal pressure being exerted on the scar in three different places. For this latter reason the incision is designated a "three in one incision," because, while the abdomen is open, it is one continuous incision, but after closure the effect is that of three distinct suture lines. The incision is begun just to the *left* and below the ensiform cartilage, and is carried downward to the middle of the fascia covering the left rectus muscle. The incision is lengthened downwards along this muscle to within two-thirds of a centimetre of the umbilicus, when it is carried straight across the midline to the right rectus muscle and downward along that muscle for four-sixths of a centimetre. The anterior surface of the *left* rectus muscle is cleared of fat, and the fascia is cleared in the transverse and right rectus incisions. The fascia on the inner third of the left rectus is then split along the length of the incision, and a transverse incision made from one muscle to the other, the fascia on the inner third of the right rectus muscle then being opened. The muscles are rolled outward and the peritoneum is opened behind the *left* rectus muscle; a transverse incision through the peritoneum just above the umbilicus completes the incision, and gives ample exposure for any operation in the upper part of the abdomen. For closure the patient is placed in a flexed position, the transverse incision being closed before the peritoneum is sutured. This suture imbricates the upper and lower flaps securely with two or three mattress sutures; the peritoneum of the upper part of the wound is then closed separately, and the muscles are allowed to drop back into their sheaths, when

the aponeuroses are sutured in the usual manner. It is claimed that this incision lessens the number of post-operative hernias; only a few twigs of nerves need be severed, and no muscle fibres are cut.

268. Carcinoma of the Lung.

W. H. CROHN and B. WEBER (*Med. Klinik*, August 2nd, 1929, p. 1209) point out that whereas of late years the morbidity of tuberculosis has decreased, the frequency of deaths from carcinoma is much greater; this is partly explained by the assistance in diagnosis which is now rendered by *x* ray examination. The authors describe eleven cases of carcinoma of the lung which came under their observation last year; ten of these cases were in men. The ages of the patients ranged from 40 to 71, the mean being 50 years. In all these patients the pain was very variable, but generally slight. In one case in which the ribs were completely destroyed and could be cut like wax, the patient had but little pain and needed only small amounts of narcotic. The temperature assumed two distinct types: some patients were entirely free from fever until one or two days before death, when there was a sudden rise; others had intermittent or remittent fever, and just before death were free from fever. The authors remark that the fever is caused by a flooding of the body with toxin; while the body has strength to make antitoxin the appearance of the fever is delayed; it is always an unfavourable symptom. The toxin is cited as the probable cause of the general illness, presenting symptoms resembling those of the last influenza epidemic, especially stomach disturbances. The sputum in some cases was blood-stained, in others it showed nothing remarkable, and severe haemorrhage was rare. Secondary pleural exudation occurred in some cases, but this was never haemorrhagic. Dyspnoea was variable, but as a rule astonishingly slight. In most cases the growth commenced in the hilus of the lung. Metastases were sometimes absent, but in some cases were present in the liver. The authors urge the importance of early examination by *x* rays as an essential to diagnosis.

269. Tonsillitis and Appendicitis.

W. M. HUNT (*Amer. Journ. of Surg.*, June, 1929, p. 761) considers the question of the possible relationship between chronic tonsillitis and an inflamed appendix, and quotes a case in which the two conditions had occurred simultaneously. An apparent relationship exists between preceding disease of the respiratory tract and a following appendicitis, and also between acute rheumatism and appendicitis, and as tonsillitis frequently precedes rheumatism the etiological connexion of tonsillitis with appendicitis is apparent. Acute infections lower the resistance and serve as a primary source of infection in appendicitis, and it is probable that the localization in the appendix is due to this lowered resistance as well as to the development of a selective strain of the micro-organism. An analysis was made of 95 cases of appendicitis admitted to hospital, and 46 per cent. of cases were found to have an acute throat condition, and the more dangerous form of appendicitis occurred in cases in which the tonsils were present and which had a sore throat on admission. Out of 34 cases of acute and chronic tonsillitis and peritonsillar abscesses, 5 cases, or 14.5 per cent., showed tenderness in the right lower quadrant.

270. Post-operative Hyperpyrexia in the Infant.

R. BERTOIN (*Journ. de Méd. de Lyon*, July 20th, 1929, p. 467) discusses the syndrome of pallor and hyperpyrexia with a rapidly fatal termination, following on an operation on an infant, usually for an acute mastoiditis. The pathology is obscure. Acute necrosis of the medullary zone of one suprarenal was found at one post-mortem examination. There is some clinical evidence that adrenaline is of value as a prophylactic. The author reports the case of an infant, aged 11 months, whose left mastoid he curetted under ether anaesthesia. Fifteen hours later the temperature rose to 106°F. The child did not react to cold packing, or injections of adrenaline and of camphor, and, empirically, a lumbar puncture was performed. The fluid, though under tension, was clear and showed no abnormality on examination. The child's condition improved, but relapsed in a few hours. A lumbar puncture was again performed and the fluid was still found clear. Considerable improvement followed, and the infant subsequently made a good recovery. The author suggests that in this case there was increase of intracranial tension caused by a diffusion of toxins, or by the action of the sympathetic on the heart-regulating centre in the mes-encephalon. There have been described a marked dilatation of the lateral ventricles in one case, and intense congestion of the encephalon with internal and external hydrocephalus in two other cases. The author observes that lumbar puncture is obviously well worth trying in similar cases, and recommends that the pressure of the cerebro-spinal fluid should be recorded over a series.

Therapeutics.

271. Serum Therapy in Typhoid Fever.

A. RODET (*Paris Méd.*, July 27th, 1929, p. 81) discusses the use of the serum he has prepared; it is obtained from horses immunized intravenously with broth cultures of Eberth's bacillus. He insists on care being observed in its administration, and mentions the following points. The serum should be given as soon as possible; there is no contra-indication. The number of injections, the interval between them, and the doses should be adapted to the necessities of each case. An injection is held to be indicated forty-eight hours after the preceding one if there has been no definite fall of temperature, and after a longer period if the temperature, having fallen, rises again or is stationary. It is not advisable to give an injection if the temperature is falling. The number of injections is frequently three, fairly often two, sometimes one, but, if necessary, four or even five. In severe cases 25 to 30 c.cm. are necessary instead of the usual 20 c.cm.; succeeding doses should show a similar increase. Excessive dosage is inadvisable and may lead to accidents. This treatment, it is added, should be exclusive; there must not be associated with it any form of cold packing or douching. Infections of the paratyphoid B group often resist it, and so do mixed infections, common secondary organisms being the streptococcus, enterococcus, staphylococcus, *B. pyocyaneus*, and *B. perfringens*. The author suggests that, as the recent epidemic at Lyons was ascribed to a grossly contaminated water supply, the cases which did not react to his serum were probably those of mixed infections.

272. Prolonged Mercurial Treatment in Syphilis.

SPILLMANN (*Bull. Soc. Française de Derm. et de Syph.*, June, 1929, p. 541) has treated a large number of patients who had contracted syphilis thirty years or more previously, and who had never been given arsenic or bismuth. Many of these patients had married five or six years after infection, and have healthy children. Very many of them continue to come for further treatment once or twice a year, or at longer intervals. Some are treated by inunction, others have injections of soluble or insoluble preparations of mercury; the majority of the latter class receive injections of grey oil. Many of these patients have not experienced inconvenience from the disease, other than the necessity to submit to periodical courses of treatment. In a number of these cases recent serological tests were uniformly negative. Spillmann gives details of five typical cases; these patients had remained free from all clinical and serological symptoms of syphilis for many years, but the author admits that he cannot give complete statistics of successful and unsuccessful treatment. He holds that the old prolonged mercurial treatment has not been superseded by modern methods, and refers to the generally admitted fact that during the last decade there has been an increased percentage of grave cases of neuro-syphilis and of general paralysis occurring in young subjects treated during or since the war by means of arsenical preparations. He contrasts this with the good results obtained from mercurial treatment, applied strictly in conformity to Fournier's rules.

273. The Treatment of Oriental Sore.

ORIENTAL sore, cutaneous leishmaniasis, is an unsatisfactory ailment to treat, according to A. DOSTROWSKY (*Arch. für Schiffs- u. Tropen-Hygiene*, August, 1929, p. 417), who has seen 200 cases, and discusses 70 he has followed more closely. The sore tends to recover spontaneously in nine months or so, and since the effect of treatment is rarely rapid, it is difficult to be sure how far the result is due to Nature or art. Native patients think it best merely to tie a leaf over the sore; cases so treated have been known to recover, and the popular impression is that scientific treatment only delays healing. That the sore tends to heal ultimately suggests the gradual development of immunity, and Dostrowsky commends vaccine therapy, referring to the paper by R. Row on the treatment of this condition by a vaccine of *Leishmania tropica* (*Journal*, 1912, vol. i, p. 540). Of ten patients so treated, two recovered in two to three months; the remainder did not complete their courses. There was improvement after each dose, but several sterile abscesses occurred; it is hoped that a more perfect vaccine may be prepared. With salvarsan injections nine patients recovered in 45 to 90 days, but there were two failures, of which one (with 158 not yet ulcerated nodes) cleared up after ten tartar emetic injections. The other patient, a man aged 60, resisted salvarsan and *x*-ray treatment, being cured promptly with tartar emetic, after the condition had lasted two and a half years. Under intravenous tartar emetic treatment nineteen patients recovered after 90 days on the average, though the nausea and pain along the vein caused complaint. Under *x* rays thirty patients became well within 30 to 120 days, and

there was only one failure, but the scar left was more conspicuous than after salvarsan or antimony. Solid carbonic acid cured ten patients in 60 to 90 days, but it is painful and its use is awkward for the patient. Until a good vaccine is found Dostrowsky thinks x rays, if available, are the best, for, though expensive, they cause no pain; otherwise salvarsan, antimony, or carbonic acid snow is likely to give the best results.

Neurology and Psychology.

274. General Paralysis of the Insane.

STATING that general paralysis of the insane is much more prevalent than is considered, E. AUBRY (*Rev. Méd. de l'Est*, April 1st, 1929, p. 173) emphasizes the great importance of its early diagnosis and treatment. Diagnosis is often difficult, as the early symptoms are extremely varied. Purely somatic cases with a retention of intellect occur, as also do others in which mental troubles are almost the only symptoms. Certain forms commence brusquely with clear signs of agitation and convulsive crises; others begin with neurasthenic depression, while in cases of insidious onset the disease develops slowly for months or even years without marked symptoms. General paralysis is not a disease solely of ripe age, but may occur in very young as well as old persons. It appears at any stage of syphilis, though usually occurring between the eleventh and sixteenth years of the disease; it may be observed much earlier (the fourth year) or much later (twenty years after the appearance of the chancre). It is common in hereditary as well as in acquired syphilis. Aubry declares that certain occupations, especially those entailing loss of sleep or conducing to intemperance, predispose to general paralysis. As the classical symptoms are seen only when the paralysis is established, for early diagnosis recourse must be made to examinations of the blood and particularly of the cerebrospinal fluid. The presence in the latter of specific reactions, lymphocytosis, and hyperalbuminosis, together with the clinical symptoms, establishes the diagnosis. Cerebral syphilis is not incurable if treatment is begun early and continued for a long period, and especially if shock therapy, such as malaria, tuberculin, or that of Dmelcos, be added to the arsenical treatment. Aubry believes that lumbar puncture during the first years of syphilis is the most effective means of preventing the development of general paralysis. The supervision of patients and continuance of their treatment long after the time usually considered necessary are the only methods of protection against dangerous sequels. It is unwise to limit treatment to nervous localizations.

275. An Heredo-Familial Disease Resembling Disseminated Sclerosis.

F. R. FERGUSON and M. CRITCHLEY (*Brain*, July, 1929, p. 203) record a clinical study of a peculiar familial affection which does not conform to any particular well-defined clinical group. Two points are noteworthy in these cases, the first being the large number of individuals affected (13); they all belonged to one family, the affection involving at least two generations. The second point is that several members of the family have been diagnosed as suffering from disseminated sclerosis. As regards the remote ancestry, there had been an intermarriage of cousins two generations before the first known affected line. The disease apparently started in two brothers, though it appears that one, if not two, predecessors were similarly affected. Throughout this family the clinical picture is uniform, and any differences are of degree rather than of kind. The clinical manifestation in the affected members presented the following common features: age of onset of symptoms at 35 to 45; similarity in the nature and order of appearance of the symptoms; absence of remissions in the course of the disease; euphoria and emotional instability; ocular paresis, nystagmus, and at times optic atrophy; evidence of pyramidal disease; widespread sensory disturbance; certain extrapyramidal manifestations; articulatory defects, and disturbance of the sphincter control. There appears to be no obvious association between the age of onset and the duration or severity of the symptoms. The duration of the disease in the fatal cases was five years in two, and seven and ten in two others; in a fifth, death occurred from an intercurrent disease at the end of one year. Of those still living, symptoms have existed in one case for sixteen years, and in four others for ten years or more. A survey of this family shows at one end of the scale cases almost indistinguishable from Parkinson's disease, and at the other cases simulating disseminated sclerosis; while other patients show various combinations of the features of these two diseases. After discussing the various familial diseases to which this condition might belong, Ferguson and Critchley conclude that there are three diagnostic possibilities with regard to it: the cases may be examples of a new familial disorder; they may be atypical examples of an already described ataxia—as, for example, Marie's ataxia; or they may be associated with Raymond's unitary conception of the heredo-familial ataxias, and grouped with the disorders described by Friedreich and others. The cases are of value in illustrating how in one family different clinical pictures, resembling almost any known type of heredo-familial ataxia, may result from a variation in the relative affection of the different systems, all of which were affected in most cases to some degree. In the absence of pathological evidence—both in these cases and those recorded in literature—Ferguson and Critchley are unable to confirm their suggestion as to the possible unity of heredo-familial ataxias, but are probably justified in regarding them all as abiotrophies differing merely in anatomical incidence or in viability.

276. Rigidity of Olivary Origin.

REMARKING that the normal functions of the olivary bodies are little known, G. GUILLAIN, P. MATHIEU, and I. BERTRAND (*Ann. de Méd.*, May, 1929, p. 460) report a case in which rigidity followed lesions of these structures. The patient, after a sudden seizure, plainly showed bulbar symptoms with involvement of all the left cranial nerves from the fifth to the tenth. Some weeks previously the man had suffered from a short attack of unconsciousness with a slight, transient left hemiparesis, due probably to a small vascular protuberantial lesion. After ten months the bulbar troubles still persisted with difficulty of deglutition and phonation, paralysis of the superior pharyngeal constrictor, hypoaesthesia of the face, the external auditory canal, the soft palate, and of the pharynx on the left side. Gradually a generalized and symmetrical hypertonic rigidity of an intensity greater than that of post-encephalitic Parkinsonism developed. This was accompanied by katatony and regular, weak tremors of the upper limbs. Bradykinesia was also very marked. The patient eventually died owing to bronchopneumonia. At the necropsy no lesion of the cortex or central grey nuclei was noted. A left lateral bulbar softening was found which had destroyed the lower part of the olivary body and the lateral bundle of the bulb. This softening, which reached the restiform body, crossed all the roots of the mixed nerves. The right olivary body showed a marked sclerosis. The authors discuss very fully the connexion of the pathological with the clinical findings, and the relations of the olivary bodies to the cerebellum and central grey nuclei. They believe that symptoms of rigidity and hypertony can arise without any important lesion of the grey nuclei; that lesions of the olivary bodies can cause general rigidity, katatony, bradykinesia, and certain tremors similar to those seen in Parkinsonian syndromes; and that these bodies play a part in the reflex and tonic actions which regulate and assure the automatism of the erect posture.

Obstetrics and Gynaecology.

277. Treatment of Cervicitis and Endocervicitis.

WHILE mercurochrome has been recommended as an antiseptic in genito-urinary infections, F. HELVESTINE, jun., and F. A. FARMER (*Amer. Journ. of Obstet. and Gynecol.*, July, 1929, p. 68) maintain that, for the successful treatment of cervicitis and endocervicitis, the mere introduction of the solution into the cervical canal is insufficient, and that it should be carried to the base of the cervical glands where the infecting germs are harboured. In the method they advocate a 2 per cent. aqueous solution is injected into the tissue of the cervix on its four sides, and sometimes between these points. From 1/2 to 3/4 c.cm. is introduced at each treatment. A few drops of mercurochrome are passed into the tissues at each puncture, and the injection is continued as the needle is withdrawn; if this is done under too much pressure pain is caused. At subsequent treatments injections are made between the points used at previous treatments. The best results are obtained with five- to seven-day intervals between treatments. The results obtained in thirty cases of inflammation of the cervix are given. In no case was there evidence of sloughs, abscesses, or other untoward effects, and the pain caused by the injections is said to be negligible if the needle is kept out of the stroma. Results are obtained quickly and the number of treatments required varies directly with the extent of the disease present, ranging from five to fourteen. Cases of specific infection do not respond as readily as those of non-specific origin. F. M. ENDE (ibid., p. 72) believes that, from the good results obtained after destruction of the pathological endocervix by heat, this method should be employed in most cases. The results of cauterization and diathermy by the ordinary active and inactive electrode method are uncertain. Ende advocates the use of two active electrodes of such a size that they can lie in the cervical canal side by side, making contact with the mucous membrane from the internal to the external os.

This method eliminates all uncertainty, and the results obtained in 200 cases were most satisfactory. In diathermy by this technique it is not necessary to remove the mucus from the canal; its presence provides good electrical contact between electrode and tissue. The treatment is the least painful of all heat methods; healing is prompt when the diseased part is entirely eradicated. The resulting scar tissue is negligible, and is softer than after cauterization.

278. Chronic Posterior Parametritis.

IN this condition, which according to E. KEHRER (*Münch. med. Woch.*, May 17th and 24th, 1929, pp. 826 and 884) has received insufficient consideration from gynaecologists in the past, one or both utero-sacral ligaments are converted into thick, tense, tender, inelastic bands sometimes as thick as a pencil, the amount of connective tissue being much increased relative to the elastic fibres. The condition, though of frequent occurrence (according to L. Fraenkel it was present in 60 per cent. of his gynaecological cases), should be carefully distinguished from posterior perimetritis, from pelvic peritonitis, in which the floor of the pouch of Douglas is involved, and from nodular adenomyositis of this region. Kehrer discusses the various theories of etiology which have been put forward from time to time, and finds little evidence in favour of true inflammation, since a history of acute bacterial infection, puerperal or gonorrhoeal, or an abscess in the pouch of Douglas following a perforated appendix, is rare in these cases. He favours, however, and elaborates the suggestion first put forward by B. S. Schultze in 1876, and since disputed or ignored by numerous authors, that one of the most important factors in initiating the pathological changes in the utero-sacral ligaments described above is repeated trauma to the posterior parametrium during coitus. This may be due to an abnormally short vagina associated with a general hypoplasia of the female genital organs or to a low position of the utero-sacral ligaments of a retroverted or partially prolapsed uterus. The type of constipation in which the rectum is loaded with hard scybala will also push the utero-sacral ligaments downwards and forwards into a position in which they are more likely to be damaged. Other etiological factors on which Kehrer lays much stress are dyspareunia of psychical origin, and other causes such as masturbation and coitus interruptus, whereby the pelvic organs, including the parametrial tissues, are congested with blood and lymph, but the normal orgasm fails to occur in the female. The symptoms are backache and a feeling of pressure in the pelvis, which may be exacerbated by physical exertion, change in position, or defaecation, and sudden pain deep in the pelvis during coitus which must be distinguished from tenderness of the vaginal orifice. The author bases his treatment entirely on the above conception of etiology, and considers incision or excision of the tender ligaments physiologically unjustifiable. He claims good results from remedying intestinal and rectal stasis by diet, drugs, or enemata, and treatment of the dyspareunia by general advice rather than psycho-analytical methods; he suggests that the impact of the penis against the tender parametrial tissue through the posterior fornix should be prevented by placing a firm cushion, 1 to 2 cm. in size, on the symphysis pubis during intercourse.

279. Carcinoma of the Fundus of the Uterus.

L. J. STACY (*Surg., Gynecol. and Obstet.*, July, 1929, p. 43) points out that while carcinoma of the fundus of the uterus has been generally regarded as a disease of post-menopause life, recent studies indicate that it occurs fairly frequently in women under the age of 50. Thus, of 333 cases operated upon for this condition at the Mayo Clinic during a period of sixteen years, 35 (10.51 per cent.) were between 45 and 49, and 35 (10.51 per cent.) were below 45, the youngest being 19. Stacy remarks that a patient with a history of metrorrhagia or abnormal discharge should be thoroughly examined before treatment is instituted. If the cervix shows no evidence of disease, a diagnostic curettage with microscopic examination should be performed under anaesthesia, followed by hysterectomy while still under the anaesthetic if carcinomatous tissue is present. Hysterectomy even with or without previous curettage is advisable if the symptoms point definitely to malignancy. In this series of cases metrorrhagia was the most usual symptom and was the first to be noted in 63 66 per cent. Uterine myoma is three times more frequent in women with carcinoma of the fundus than in those without this condition, and there is a possibility of the symptoms being attributed to the myoma, thus leading to delay in making a correct diagnosis. The post-operative results were better than those following operation for malignancy in other commonly affected organs, 184 patients living more than five years (63.88 per cent.). The operative mortality for the series of 333 patients was 18 (5.4 per cent.), and the largest mortality from recurrences occurred during the first three years after operation.

Pathology.

280. The Relation of Bacteria to Chemically Induced Pneumonia.

A. R. KOONTZ and M. S. ALLEN (*Journ. Exper. Med.*, July 1st, 1929, p. 67) cite the contradictory opinions of various authorities as to whether the pneumonia resulting from inhalation of irritating substances is due purely to the chemical agents inhaled or to the action of bacteria, and record their study of the lungs of a number of dogs tested with different gases. No definite conclusion could be drawn from this study concerning the causal relation of bacteria in gassed lungs to the pneumonia present. The appearance of gassed lungs with pneumonia was very similar to those with pneumonia of known bacterial origin. In a few cases the type of pneumonia coincided with reported cases of chemically induced pneumonia, which is characterized by a preponderance of epithelial cells in the exudate. Gassed lungs show highly varying numbers of bacteria, which are not intracellular and are not present in large numbers in the majority of cases. Points against a causal relationship are: the early appearance of pneumonia after gassing; the occurrence of pneumonia with very small numbers of bacteria present; and the fact that very few bacteria are engulfed by leucocytes in gassed lungs, whereas large numbers are present in non-gassed pneumonias and are conspicuously intracellular. The points in favour of a causal relationship are: the presence of bacteria in any numbers; the picture of broncho-pneumonia presented is similar to broncho-pneumonia of known bacterial origin; and pneumonias characterized by large numbers of epithelial cells in the exudate (so-called "chemical" pneumonia) occur in animals that were never gassed or subjected to other irritating substances.

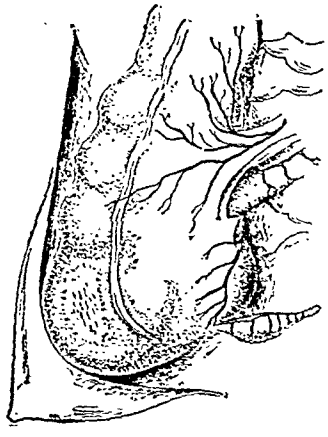
281. The Serological Affinity of Vibrion septique and Clostridium chauvoei.

M. WEINBERG, J. DAVESNE, M. MIHAILESCO, and C. SANCHEZ (*C. R. Soc. de Biologie*, July 17th, 1929, p. 907) have compared a number of strains of *V. septique* and *Cl. chauvoei* by the complement-fixation test. The antigens used were prepared from broth cultures which were centrifuged, and heated at 60°C. for one hour; in one series, however, the alcohol-ether method of Nicolle was used. The antiserums were prepared by the inoculation of rabbits with cultures that had been heated at 60° C. for one hour. In the first series of experiments it was found that each of fifty strains of *Cl. chauvoei* was able to fix complement in the presence of anti-*septique* serum, even when this was diluted 1 in 100. The amount of fixation that occurred was very nearly as great as when antigens of *V. septique* were employed. In a second series it was found that *V. septique* was able to fix complement in the presence of anti-*chauvoei* serum, even when this was diluted 1 in 100 or sometimes 1 in 200. A similar degree of fixation was given by *Cl. chauvoei* in the presence of its homologous serum. Antigens prepared from *Cl. histolyticum*, *Cl. oedematiens*, and *Cl. sporogenes* gave negative results, even with pure serum. *Cl. welchii* gave a positive reaction in the presence of the pure serum, but not when this was diluted 1 in 10. The authors conclude that it is impossible to distinguish *V. septique* and *Cl. chauvoei* by the complement-fixation test; but this reaction is specific, and enables a differentiation to be made between these two organisms and the other members of the spore-bearing anaerobes.

282. Immunization against Tuberculosis.

M. BECK (*Münch. med. Woch.*, June 28th, 1929, p. 1032) has protected [illegible] by virulent human tubercle [illegible] tubercle ointment, which was prepared from subcultures of originally highly virulent human tubercle types which had lost the power to cause tuberculosis, yet possessed in high degree an immunizing and healing action on tubercle-affected organs. A series of twenty-three guinea-pigs were inoculated subcutaneously with an emulsion of highly virulent human tubercle bacilli; three of these were regarded as controls. After tuberculosis had been established in all the animals, according to clinical and microscopical evidence, the remaining twenty animals received, during a period of several weeks, six to ten inunctions of the ointment into the previously shaven skin. The guinea-pigs were killed after various intervals of nine days to one month. Tubercle bacilli were detected in three instances, but in the remaining animals, many of which had enlarged glands, tubercle bacilli were not found. The three control animals not treated with inunctions survived a longer period, all being dead after seven months, and all showed presence of tuberculosis in the lungs, liver, and spleen.

Among the Results of Constipation



Distended and sagging cæcum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxæmias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL Brand Compound, combining three essential actions: lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted fæces, generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol Brand Compound assists the organism back to regular normal evacuation by restoring *peristaltic function.*

The dependability of Agarol Brand Compound has definitely enlisted the interest of the medical profession, who in most cases of acute or chronic constipation, successfully prescribe Agarol Brand Compound — one tablespoonful on retiring.

A Liberal Quantity For Trial To Physicians

Clothes by KEITH BRADBURY *including Ladies' Tailor-Mades*

Overcoats *for* Autumn

£1 PER MONTH

Summer days are speeding away, the evenings are becoming chilly and instinctively one seeks the warmth and comfort of an overcoat. Dinners and dances, too, are taking the place of evening golf and tennis, and many suits of dress clothes, shabby or green with age, will need replacing.

A new overcoat, new dress wear, and perhaps a new lounge suit for the winter would cost at least 16 guineas, and how many men feel disposed to write a cheque for this amount so soon after the holidays, especially Doctors, who have to depend upon the financial recuperation of patients for payment of their accounts.

It is through the difficult times, such as now, that Keith Bradbury's system proves its usefulness, by enabling a Doctor to replenish his wardrobe with West End tailored clothes at attractive prices upon a monthly basis of payment, to suit his individual requirements.

Keith Bradbury, Ltd., have served the medical profession long enough to know that references and enquiries are superfluous—and to provide the usual cash or quarterly facilities for those who prefer them.

The appearance of medical men should be in keeping with the prestige of the profession, and it costs you nothing to write, to telephone, or call for full particulars of Keith Bradbury's £1 per month system of tailoring, which is helping an ever increasing number of Doctors to dress well without financial inconvenience.

Overcoats and Lounge Suits	from 5 gns.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received *without Certificates*.

For terms, etc., apply to the Medical Superintendent.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) Ch.M.EDINBURGH. M.C.CANTAB.
F.R.C.S.EDINBURGH. M.S.LONDON.
And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.
¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

M.D. THESIS

(Camb., Edin., Glasg., Durh., &c.)

SKILLED COACHING, GUIDANCE, and ADVICE From Specialist Tutors, in conformity with the Regulations of the various Universities. Apply for particulars and free booklet, "Hints on Writing a Thesis for the M.D. Degree," to the SECRETARY, Medical Correspondence College, 19, Welbeck Street, London, W.1.

Glamorgan County Council.

APPOINTMENT OF MEDICAL OFFICER.

The Glamorgan Education Committee invite applications for the appointment of a Male *Medical Officer*. Applicants must have had at least three years' professional experience after qualification, and also hold a Diploma in Public *Health*. Special experience in Eye Diseases and Refraction work is essential, and experience in Orthopædic work would also be an advantage. Candidates must not be over 35 years of age.

The commencing annual salary will be £632 10s. less 5 per cent., and after three years will be increased to £641 5s., and thereafter by annual increments of £23 15s. to a *maximum* of £760.

Travelling and subsistence expenses will be paid according to scale.

The post is an established post under the County Superannuation Scheme, and for this purpose a deduction of 5 per cent. of the annual salary will be made, repayable with interest on retirement before pensionable age.

The person appointed will be required to give his whole time to the *duties*, under the control and supervision of the School Medical Officer, and to reside where directed by the Committee.

The appointment will be terminable by two months' notice on either side.

Applications for the appointment, stating age and qualifications, and accompanied by copies of not more than three *recent* testimonials, should be sent to the School Medical Officer, Dr. E. COLSTON WILLIAMS, County Hall, Cardiff, and should be received by him *not later* than the first post on the morning of October 2nd.

Canvassing, personal or otherwise, will be a disqualification.

Glamorgan County Hall, Cardiff.
Sept 14th, 1929.

HENRY ROWLAND, Clerk of the County Council.

University of Cape Town.

APPOINTMENT OF ASSISTANT ANATOMIST.

Applications are invited for the post of Assistant Anatomist in the Department of Anatomy at the University of Cape Town.

Candidates must have a registrable medical qualification, and must have had experience of teaching anatomy. The appointment is a whole-time one, and the holder will be expected to take a responsible share in the teaching and to undertake research.

Salary.—£750 per annum, but for pension purposes it will be regarded as being on the scale £500—£25—£650.

Salary will be paid from February 1st, 1930, provided the Assistant has vacated his previous post on or before January 31st, 1930, and reports for duty on or before February 25th, otherwise salary will be paid from date of assumption of duty.

The appointment is for a period of three years in the first instance.

Passage Money.—£50 will be allowed for passage expenses, subject to a proportionate refund in the event of the Assistant terminating his agreement within three years of the date of the assumption of duty.

Duties.—To be assumed on March 1st, 1930.

Applications, stating age, professional qualifications and experience, together with copies of three recent testimonials (all in duplicate), should reach the Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, W.C.2, from whom forms of application and further particulars may be obtained, not later than October 8th, 1929.

Medical Department, SUDAN GOVERNMENT.

A MEDICAL OFFICER is required immediately for the Sudan Medical Service. The candidate must be single and should be under 30 years of age, and he must have held a Resident appointment in a large General Hospital.

Pay commences at £E.720 a year, *rising to* £E.1,200 after thirteen years' service. On confirmatio[illegible] lected candidate wil[illegible] service.

Applic[illegible] th copies of recent[illegible] ade to Dr. HODSON, from whom, and from the Secretaries or Deans of the principal Medical Schools, further particulars can be obtained.

British Hospital, Port Said.

ASSISTANT MEDICAL OFFICER.

Resident Assistant Medical Officer required immediately. Salary £350 per annum, *rising* £400. Free quarters, board, and laundry provided, also first saloon passages out and home. Candidates should be young and unmarried. Applications, in writing, with recent testimonials, should be sent to the Secretary, British Hospital, Port Said, 19, Berkeley Street, London, W.1.

City of Westminster.

ST. STEPHEN'S HOSPITAL.

THIRD ASSISTANT MEDICAL OFFICER.

The Guardians require a Third Assistant Medical Officer (male) for their Hospital, 369, *Fulham Road*, S.W.10.

Remuneration £300 per annum, rising £25 yearly to £350 per annum, with board, residence, and washing.

Candidates must have had experience in the administration of anæsthetics, and will be required to take part in the teaching and instruction of the Nursing Staff.

Further particulars of the duties may be obtained upon personal application to the Medical Superintendent at the Hospital any day between 12 noon and 1.30 p.m., or forms of application may be obtained on forwarding to him a stamped addressed envelope.

Forms of application must be returned to the Medical Superintendent not later than 12 noon on Wednesday, October 9th.

W. J. LICKLEY,
Clerk to the Guardians.

North Ormesby Hospital,

MIDDLESBROUGH. (140 Beds.)

HOUSE PHYSICIAN required early in October. Male and unmarried. Salary £115 per annum, with board, residence, and laundry.

There are three Residents, and the successful candidate will be eligible for the post of House Surgeon in due course.

Applications, stating age, qualifications, previous experience (if any), with copies of three recent testimonials, to be sent to the undersigned as early as possible.

GEORGE WATTS, Secretary-Supt.

ROYAL NAVAL MEDICAL SERVICE.

VACANCIES EXIST FOR MEDICAL OFFICERS IN THE ROYAL NAVY.

Candidates will be entered as Short Service Medical Officers and will be considered for transfer to the Permanent Service after 6 months' service. They must be registered under the Medical Acts, and be under 30 years of age on date of entry.

Medical Officers, R.N., are liable to serve in Naval Hospitals or Ships in any part of the world.

Excellent opportunities exist for clinical professional work, both medical and surgical, as well as for study and practice of Hygiene, Pathology, Ophthalmology, and other specialist branches.

Adequate provision is made for Post-Graduate Study.

OUTFIT ALLOWANCE of £50 is paid on joining.

PAY.—Pay from £452 to £2,350 a year, according to length of service.

ALLOWANCES.—When in charge of **Hospitals** and **Sick Quarters,** 10s. and 5s. a day.

60 Specialists Allowances of 5s. a day.
Flag Allowances, 5s. and 2s. 6d. a day.
Provision Allowance, Lodging Allowance, etc.

PROMOTION.—To Surgeon Lieutenant Commander after 6 years' service; to Surgeon Commander after a total of 12 years' service. Promotion to Surgeon Captain, Surgeon Rear-Admiral, and Surgeon Vice-Admiral is by selection.

Ante-date of seniority on account of civil hospital appointments, and accelerated promotion can be gained.

RETIREMENT.—Gratuities are paid as follows:—

Short Service Officers, after 3 years' service	£300
Permanent Officers, after 4 years' service ...	£400
„ 8 „ „ ...	£1,000
„ 12 „ „ ...	£1,500
„ 18 „ „ ...	£2 250

Rates of Pension range from £423 a year, normally earned after 20 years' service, to £1,123 a year, the maximum earned by a Surgeon Vice-Admiral.

Copies of the Regulations and Particulars as to Conditions of Service and Emoluments may be obtained on written or personal application to the Medical Director General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

Birmingham Union.

SELLY OAK HOSPITAL.

RESIDENT PHYSICIAN (Male).

Applications are invited for the above post, giving age, full details of experience and qualifications and accompanied by copies of not more than three recent testimonials. Applications should be forwarded so as to reach the undersigned not later than Wednesday, October 9th.

Candidates must hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or be a Fellow or a Member of the Royal College of Physicians of London or Edinburgh.

The Resident Medical Staff, including the Medical Superintendent, numbers eight.

The present Hospital accommodation consists of 540 beds for acute cases, divided into general medical, general surgical, gynæcological, obstetrical, and children's sections. Out-patient and Casualty Departments, as well as the following fully equipped special departments, are attached to the Hospital:—Pathological, X-ray, Electro-therapeutic, Massage, Ultra-violet ray.

The admissions and discharges for the year 1928 were 7,284 and 7,448 respectively.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the Medical Superintendent and will carry out such duties as may be assigned to him by such officer with the consent of the Guardians. Should occasion arise, the successful applicant must be prepared to assist at any of the other Institutions in the Union without additional remuneration.

The commencing salary will be fixed between £400 and £600, according to qualifications and experience. If fixed lower than the latter figure, the salary will rise to that figure by £50 annually, subject to satisfactory service. The Guardians' regulations provide that at the expiration of 12 months' satisfactory service additional allowances not exceeding in all £150 per annum are granted to the holders of certain prescribed degrees and/or diplomas.

Furnished quarters, rations, laundry, and attendance, will be provided. A deduction of 2 per cent. will be made from the salary and value of the emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars may be obtained, if desired, on application to the Medical Superintendent, R. P. S. KELMAN, Esq., M.B., F.R.C.S.(Eng. & Edin.).

Union Offices, Edmund Street, Birmingham. C. P. BEECH, Clerk to the Guardians.

Kingston Union.

APPOINTMENT OF THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the Poor of the Kingston Union require a thoroughly qualified Third Assistant Resident Medical Officer at the Kingston and District Hospital (age not to exceed 30 years).

The appointment will be for six months in the first instance and may be extended subject to satisfactory service.

The salary will be at the rate of £250 per annum, with apartments, rations, laundry, and attendance (valued at £125 per annum for superannuation purposes), and will be subject to the terms of the Poor Law Officers Superannuation Act, 1896.

Applications for the post, stating age, experience, and nationality, together with recent testimonials, should reach me not later than 10 a.m. on Friday, October 4th.

Experience in administration of anæsthetics essential.

Canvassing, either directly or indirectly, will disqualify.

Union Offices, Kingston-on-Thames. September 17th, 1929. W. TAYLOR, Clerk to the Guardians.

The Royal Hospital,

WOLVERHAMPTON.
(Incorporated under Charter.)

A RESIDENT MEDICAL OFFICER WANTED.

The Hospital contains 240 beds, the usual special departments, and is recognized by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice.

Candidates must be registered under the Medical Acts.

The appointment is for six months, with a salary at the rate of £150 per annum. Board, furnished rooms, and laundry provided.

Duties to commence November 1st.

Application, with copies of testimonials, to the undersigned.

W. H. HARPER,
House Governor and Secretary.
Wolverhampton.
September 24th, 1929.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified medical practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road [illegible]

The Hospi[illegible] by the Guardians [illegible] Medical, Surgical, [illegible]ternity, Gynæcological, and Obstetrical Section. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that period.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Chief Medical Officer, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salaries and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum. Fourteen days' leave will be granted to the successful candidates during their term of office.

Further particulars of the appointments may be obtained from the Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than Wednesday, October 9th.

Union Offices, Birmingham. Sept. 19th, 1929. C. P. BEECH, Clerk to the Guardians.

University Graduate having held Hospital appointments preferred.
4. HERTS. — Better-class Country PRACTICE, within easy reach of London. Old-established, and patients are chiefly of the professional class. Average income £1,000 p.a., including panel of 480 and about £60 from appointments. Advice and medicine 3/6 to 10/6, visits 5/6 to 21/-. Not much midwifery. Exceptionally nice house, with every modern convenience and half an acre of garden. Price for freehold £2,700. Excellent sport, society, and schools. Prem. £1,500.
5. MIDLANDS.—In a clean thriving Hospital town (pop. 130,000), an old-established mixed-class PRACTICE worth last year £1,100, including panel producing over £400 p.a. and £150 from Public Medical Service. Large house, with ample accommodation, good garage, garden, etc. Vendor's leasehold having 31 years unexpired (ground rent £9 16s.). Price £1,500. Premium £1,650.
6. WILTS.—COUNTRY PRACTICE, on outskirts of large town. Well-established and producing for the immediate past year over £1,650, including panel of 1,390. Advice and medicine 3/6, visits 5/- upwards. Detached double fronted house, with good garden. Garage. Rent on lease £60 p.a. Premium £2,400.
7. NEW ZEALAND (South Island).—In a delightful and popular seaside resort (pop.: town over 17,000 and country 5,000, greatly augmented by visitors) on main line, a well-estab. PRACTICE averaging £1,816 p.a. for the past 5 years, including about £175 from Lodges. Consultations fees 10/6. Mids. 4 to 10 gns. (75 cases p.a.). House is situated in excellent position and contains 14 rooms, with 1/2 an acre of garden, tennis court, etc. Can be leased. Excellent educational facilities. Sport of all kinds.
8. LONDON, S.W.—Within easy reach of Charing Cross.—Very old-established middle-class non-panel PRACTICE averaging over £2,000 p.a. Fees 2/6 to 10/6. Mids. 3 to 10 gns. (about 12 cases). Commodious house, with 2 reception, 5 bedrooms, etc. Garden. Rent on lease £65. Premium £3,100.
9. LONDON, WEST.—Good-class General PRACTICE, held by Vendor for the past 25 years. Gross cash receipts for past three years average £1,682. Fees 10/6 to 2 guineas. Only a few midwifery cases at from 10 to 20 guineas. Good house, with 3 public and 6 bedrooms, etc. Electric light. Garden. Garage. Rent on lease £150. Premium £2,750.
10. HOME COUNTY.—Within 40 miles of London.—Good Country PRACTICE, established over 100 years, in very attractive district within 10 miles of favourite County Town. Patients include many county families. Income for immediate past year nearly £1,400, including transferable appts. worth about £120, and panel of 750, producing with mileage £470. Fees from 2/- to 21/-. Little midwifery. Facellent house, with 3 reception, 5 bedrooms, etc. Good garden. Garage. Rented on lease at £80 p.a. Premium £2,200.
11. CORNWALL.—FAVOURITE COAST TOWN.—PARTNERSHIP.—A one-third share is offered in a well-established Practice, having good surgical scope. Average gross cash receipts £4,200 p.a. Panel of about 1,800 and good appts. Very nice house available on rental, or smaller house or rooms could be taken. Hospital and prospect of appt. on staff. Premium £2,400.
12. PARTNERSHIP.—SOUTH-EAST COAST.—A one-third share (with increase later) is offered in a well-established non-dispensing Practice situated in a popular residential town and health resort. Receipts for past three years average over £3,000, with good scope. Fees from 5/- to 21/-. Very little mid. Attractive house, with 4 reception, 6 bedrooms, etc. Garden. Garage. Premium 2 years' purchase.
13. SOUTH-WEST OF ENGLAND.—SEAPORT TOWN.—PARTNERSHIP.—A one-sixth share is offered in a very old-estab. sound mixed-class Practice situated in residential outlying suburb. Average gross cash receipts for past three years over £6,700, including panel of 4,000, and appts. worth about £750. Excellent house, property of retiring partner, can be bought; or purchaser can select his own residence. Good sport and schools. Premium 2 years' purchase.
14. CARDIFF.—Old-established better-class non-dispensing worth last year about £1,400. Panel of 450. Fees from 5/- to 21/-. Very little midwifery. Good house in best part of the city. Can be rented on lease. Premium £2,000.
15. ESSEX.—Rapidly developing outlying suburb, within ten miles of the Bank.—Well established and increasing PRACTICE. Income last year £2,274. Panel of 1,646. Fees 2/6 upwards. Very little midwifery, but large scope. Very good corner house, in excellent repair, with 2 reception, 5 bedrooms, separate professional rooms, etc. Electric light. Garden. Garage. Price for freehold £1,550. Prem. £3,600.
16. SOUTH-WEST OF ENGLAND.—GOOD HOSPITAL TOWN.—PARTNERSHIP.—A one-half share in a very old established mixed-class Practice is for disposal owing to the retirement of the Junior Partner. Gross cash receipts average £2,300 p.a., including good appts. Small panel. Low expenses. Commodious house, with garden and garage. Rent £70 p.a. Vendor on staff of Hospital, and scope for surgery. Premium 2 years' purchase.
17. PARTNERSHIP.—WILTS.—A two-fifths share, with increase up to one-half later, is offered in a good mixed Practice situated in a pleasant town, with country surroundings. Income from share £900 p.a. Good scope for increase, particularly in surgery and midwifery. Cottage Hospital. Premium 2 years' purchase.
18. WITHIN 50 MILES OF LONDON.—Well-established and increasing PRACTICE situated in small country town in very pretty district. Income last year over £800, including panel of over 500, and appts. worth about £60. Visits 5/6 to 21/-, medicine extra. Exceptionally nice house can be bought, or smaller house available, which can be rented at £50 p.a. Good schools for boys. Premium 1½ years' purchase. Good scope for increase.
19. BORDERS OF WARWICK AND OXON. — Old-established Country PRACTICE, in attractive district near two good towns. Average income for past three years £1,157, including panel of 580 and appts. worth over £100. Fees 2/6 to 21/-. Good house, with 2 sitting, 4 bedrooms, etc. Separate entrance to surgery. Garden. Garage. Price for freehold £1,350. Hunting, golf, and schools within reach. Premium 1½ years' purchase.
20. SHROPSHIRE.—Unopposed Country PRACTICE, in pretty district, producing this year at the rate of about £1,400, including panel of 550, and appts. worth £65. Visits 3/6 to 7/6, with medicine and mileage extra. Midwifery from 3 gns. About 20 cases. Suitable house, with modern conveniences, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Rent on lease £100 p.a. Good sport and schools. Premium £1,500.
21. YORKS.—LARGE TOWN.—Old-established mainly working class PRACTICE. Income £1,250. Panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Prem. £1,800.
22. LIVERPOOL.—Centrally situated old-established PRACTICE. Income about £1,500. Panel of over 2,500, worked from Branch Surgery. Visits and medicine from 3/6 to 7/6. Little midwifery. Large corner house, with garden and garage. Recently redecorated. Electric light and new hot water system throughout. Price, freehold, £2,000. Large scope for increase. Premium 1½ years' purchase.
23. SUSSEX.—VILLAGE PRACTICE in delightful surroundings, at present producing over £1,150 p.a., but capable of considerable increase. Fees from 3/6 upwards. Exceptionally charming residence standing in 2½ acres of well laid out garden, and containing lounge hall, 2 reception, 7 bedrooms (3 fitted with h. and c. water basins), dressing room with fitted bath, and other usual offices. Central heating. Electric light. Garage for 2 or 3 cars. Price for freehold £4,300. Premium £1,700.
24. SOUTH-WEST OF ENGLAND.—HOSPITAL TOWN.—PARTNERSHIP.—A half share is for disposal in a good middle-class non-panel, general, and surgical Practice, averaging for the past three years over £5,000 p.a. Good house, with 2 reception, 6 bedrooms, etc. Premium 2 years' purchase. Purchaser should hold the F.R.C.S.
25. HANTS.—COUNTRY PRACTICE, at present producing about £480 p.a., but offering large scope. Panel of 280. Fees 3/6 to 10/6. Mid. from 3 gns. Convenient house, with 2 reception, 5 bedrooms, etc. Garden and garage. Can be rented on lease at £75 p.a. Premium £500 for prompt sale.
26. NORTH-WEST LONDON.—Within easy reach of Charing Cross.—Old-established mixed-class PRACTICE averaging over £2,000 p.a., including panel of about 1,400. Fees 2/6 to 10/6. Midwifery 3 to 15 gns. Six-roomed house, with bathroom, kitchen, etc. Rent on lease £85. Surgery premises (part let off) rented at £75 p.a. Could be worked as "look-up." Premium 1½ years' purchase.
27. SOMERSET.—Increasing PRACTICE, situated in very pretty district. Income last year over £900, with good scope. Panel of nearly 400, and appts. worth about £260. Fees 2/6 to 15/-. Not much midwifery from 7 to 15 gns. Good house, with 2 reception, 5 bedrooms, etc. Garden. Price for freehold £1,275, part on mortgage. Excellent sport. Schools. Premium 1½ years' purchase.
28. GLOS.—LARGE TOWN.—PARTNERSHIP.—A half share of an old-established good-class non-dispensing Practice, owing to retirement through ill health of senior partner. Income about £5,000, with small select panel. Fees 5/- to 10/6. Purchaser should be about 40, married, and keen on midwifery. Good house available at low rental. "Vitamin D: a review of present-day practice." *This interesting book will be sent to any doctor on request.*

SUNSHINE GLAXO (Humanised Glaxo with added Ostelin Vitamin D). This new food represents a great advance in infant dietetics. It contains a physiologically correct proportion of added Vitamin D (Ostelin), and clinical trials have shown that it overcomes previous difficulties of artificial feeding—e.g., constipation, lack of tonicity, and excretion of soapy stools due to excess fat. It can be prescribed in pregnancy and lactation with special advantage to mother and child.

CONSTABLE & CO., LTD.

Modern Medical Monographs

Specially written for the General Practitioner.

HUGH MACLEAN, M.D., D.Sc., F.R.C.P. (Professor of Medicine, London University), on

MODERN VIEWS ON DIGESTION AND GASTRIC DISEASE

SECOND EDITION, REVISED. 12/- net.

"It is not surprising that Prof. Hugh Maclean's volume entitled 'Modern Views on Digestion and Gastric Disease' has rapidly passed into a second edition."—BRITISH MEDICAL JOURNAL.

"The value of this book depends not so much on a wide survey of gastric physiology and pathology . . . as on the clear and concise manner in which a method of treatment, based on known facts of physiology and pathology, is set forth."—LANCET.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF GLYCOSURIA AND DIABETES

FOURTH EDITION, REVISED. 12/- net.

"Of the successful series edited by Prof. Hugh Maclean of 'Modern Medical Monographs' the first by himself on Glycosuria and Diabetes was brought out in 1922 and is now in its fourth edition, a testimony to its popularity which almost absolves the review from further comment."—BRITISH MEDICAL JOURNAL.

MODERN METHODS IN THE DIAGNOSIS AND TREATMENT OF RENAL DISEASE

THIRD EDITION, REVISED. 12/- net.

"This extremely useful handbook is both scientific and practical, and thus has rightly been recognized as a book to buy and keep at hand for reference and advice in emergencies."—BRITISH MEDICAL JOURNAL.

"This is a very useful handbook; it is written in a clear and compact manner, but at the same time gives a sufficient description of all the new work on the subject of importance; it will be much appreciated by the busy practitioner."—JOURN. OF STATE MEDICINE.

***VOLUMES ON MANY BRANCHES OF MEDICINE ARE INCLUDED IN THIS SERIES OF MODERN MEDICAL MONOGRAPHS, EACH VOLUME BEING DESIGNED SPECIALLY TO MEET THE REQUIREMENTS OF GENERAL PRACTITIONERS. WRITE FOR A PROSPECTUS.

10 & 12, Orange Street, London, W.C.2.

Subscription in India and abroad Rupees 16 *per annum. Post free. Payable in advance.*

THE INDIAN JOURNAL of MEDICAL RESEARCH

EDITED BY

THE DIRECTOR-GENERAL, INDIAN MEDICAL SERVICE, THE PUBLIC HEALTH COMMISSIONER WITH THE GOVERNMENT OF INDIA, AND THE DIRECTOR, CENTRAL RESEARCH INSTITUTE, IN COLLABORATION WITH

leading authorities on Tropical Medicine.

The Indian Journal of Medical Research is published quarterly. Each number contains about 200 pages, and is illustrated with Plates in Colour and Half-tone, and with Diagrams and Charts, and is the only medium publishing the results of the best medical research work being carried on by leading scientific medical men in India and the East.

SELLS

Your Quartz Lamp-

Use it on Yourself

One of the leading specialists in actinotherapy recommends daily irradiation for the doctor himself. He writes: "After irradiation we experience a feeling of well-being, freshness, a renewed pleasure in social intercourse and deeper sleep. The doctor, who restores his weary nerves at evening by this means, will soon come to cherish the light bath and will not readily give up the habit."

Irradiation with the Hanovia Quartz Lamp gives increase of muscular and nervous energy and increased mental and physical working capacity without fatigue. Quartz Light is a valuable adjuvant in the re-oxygenation of the blood and greatly assist excretion of fatigue toxins from the tissues.

163,000 Hanovia Quartz Lamps are in use to-day. Write for reprints on your own branch of medicine.

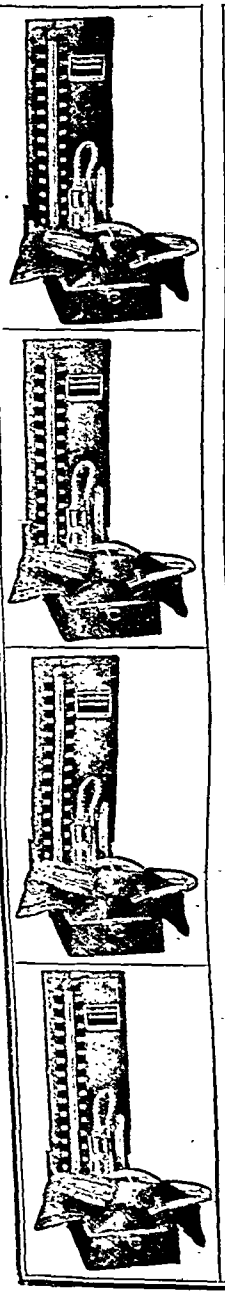
SPECIALIZATION in this one field of endeavor—bloodpressure apparatus—has enabled us to attain in the *Lifetime Baumanometer*, the highest degree of *Accuracy—Simplicity—Permanence—Beauty*—the four chief essentials of modern bloodpressure instruments. Under these headings we list the many innovations and refinements that insure these in faithful performance to Baumanometer owners.



Scientific Accuracy

Every *Lifetime* Baumanometer is individually calibrated, scientifically accurate and GUARANTEED to remain so—accurately interchangeable glass Cartridge Tube and standardized steel reservoir—stabilized mercury column—no oscillations—no mercury spilling—minimum oxidation—readily cleanable tube and reservoir—calibrations directly on tube, white background for mercury—most easily read scale and tube and *a full unobstructed scale reading from 0 to 260 or 300 mm.—no parallax errors. A master instrument!*

Utmost Simplicity

Instantly ready for use—no adjustments, attachments, or fitting several parts together—one compact, EASILY PORTABLE unit—positive control over mercury column—equally practical for desk or out side use. *The essence of simplicity!*

Real Permanence

Glass Cartridge Tube GUARANTEED AGAINST BREAKAGE FOR YOUR LIFETIME (a written guarantee is given to every purchaser)—entire manometer unit encased in metal and *chromium-plated*—no cemented joints—no friction points—nothing to get out of order—nothing to wear out except pure gum tubing and bag and English handmade pure gum Baumanometer bulb which will last for years. *A truly lifetime apparatus!*

Well-Proportioned Beauty

Hand-rubbed solid walnut case—beautiful ivoroid scale—the result of years of specialized endeavor to perfect an instrument of correct proportion, design, and construction. *A beautiful and modern piece of equipment!*

You Couldn't Expect More—

GLASS ELECTRODE APPARATUS

FOR

pH MEASUREMENTS OF BLOOD

The illustration shows a complete outfit for determining the pH of blood by the glass electrode method developed by Dr. Phyllis M. Tookey-Kerridge. A thin glass membrane separates the sample being tested from a buffer solution of known pH and the difference of electrical potential is measured by a direct-reading potentiometer, a Lindemann electrometer being used as a null point indicator. Only a small quantity (about 0.5 c.c.) of the sample is required, and there is no need for carboxylation. Full details are given in List No. L-910.

Workers in Industry Feel the Need of Dependable Supports.

Men and women in industrial plants where the work done involves constant standing or great muscular strain frequently ask their physicians to recommend a sturdy, light weight, comfortable, and dependable support to relieve strain upon abdominal muscles, to secure them against hernia, or to relieve them from sacro-iliac relaxation or sacro-iliac strain.

For many years physicians have used Spencer belts, similar to the one shown in the illustration on this page, to meet the needs of men and women in industry.

Each Spencer belt is especially designed to meet the particular needs of the individual who is to wear it.

All Spencer belts are made with a back wide enough to prevent the support from changing position, even during the most vigorous activity. Comfort as well as security is assured by the wide back of the belts, whether for men or women. A Spencer belt will not cut into the flesh as does a narrow belt.

Adjustment of the Spencer belt is made quickly and easily by pulling the straps which run through self-locking buckles on each side near the front.

The belt is non-elastic. It has no heavy metal parts. It is washable and durable. It gives comfort, security, and adequate support for the back and abdomen.

The Spencer Corsetière will gladly call at your surgery or at your patient's home, to take measurements under your supervision. If her address is not known to you we shall be happy to supply it.

We issue the following booklets on the uses of Spencer Supports: Pregnancy and Post-partum Support, Sacro-iliac Strain, Hernia, Movable Kidney. We will gladly send you any of them in which you are interested.

THE London Medical Exhibition

(Established 1905)

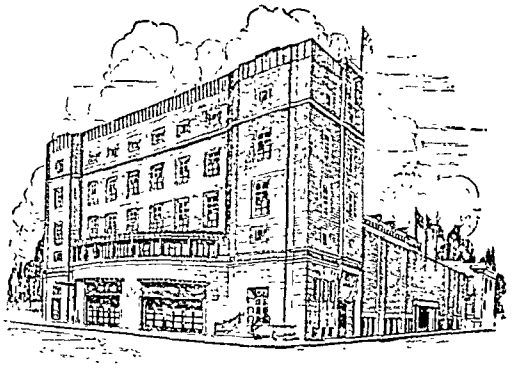
The NEW HALL of the ROYAL HORTICULTURAL SOCIETY, GREYCOAT STREET, WESTMINSTER, S.W.

Monday, Tuesday, Wednesday, Thursday and Friday, October 14, 15, 16, 17 and 18, 1929.

From 12 noon till 6.30 p.m. Daily.

Organised by the Management of the Exhibition of the 17th International Congress of Medicine, 1913, and of the Fifth Clinical Congress of Surgeons, 1914.

THE LARGEST EXHIBITION YET HELD



EXHIBITION BUILDINGS.

STRICTLY CONFINED TO THE PROFESSION

The attention of the Profession is drawn to the fact that owing to the continued growth of the Exhibition, both in number of Exhibiting Houses and also in the attendance, it has been found necessary to move into a larger building. The New Hall of the Royal Horticultural Society is a magnificent structure offering every modern advantage and specially suitable for a Professional Exhibition. All exhibits will be on one level.

The lighting, both natural and artificial, is on novel lines and of the highest efficiency.

The exhibits will be more numerous and varied even than in the past. A spacious and well-fitted Reception Room overlooks the Exhibition Hall, and here an orchestra will perform each day and visitors will be entertained to afternoon tea.

Invitation cards will be sent to every member of the Profession residing in London and in Counties adjacent thereto. Practitioners desiring to visit the Exhibition who do not receive cards can obtain same on application to the Secretary, the London Medical Exhibition, 194-200, Bishopsgate, London, E.C., or at the Hall during the Exhibition week.

GASTRONOMICS

A.D. 70 **A.D. 1929**

"*Touching the paunch or belly*," *says Pliny, according to his English translator, Dr. Holland,* "*much ado there is with it; and although most men care for nothing else in this life but to content and please the belly, yet of all parts it putteth them to the most trouble. For one while it is costive, as that it will give no passage to the meat, another while so slipperie as it will keep none of it; one time you will have it so peevish as that it can receive no food, and another time so weak and feeble that it is able to make no concoction of it.*"

Pliny's observations on gastro-intestinal disorders do not differ greatly from those of medical men practising to-day, except in the quaintness of the old English translation; but the knowledge of the causes of fermentation and putrefaction gives the twentieth century an advantage in treatment not possessed by any preceding one. To limit the violence of chemical changes produced by harmful bacteria is the aim of every therapeutic measure for the benefit of alimentary disabilities, and in the bactericide Dimol the medical profession has recognised this great new assistance at their disposal.

After long and thorough investigation, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

Local Anæsthesia in Surgical Practice

PULMONARY ABSCESS.
(RIB RESECTION.)

Typical Case.

C. R. female, aged 19 years, pregnant.

Diagnosis: Pulmonary abscess.

Operation: Costectomy; drainage and Beck's plastic.

Anæsthesia: Local infiltration and paravertebral intercostal block.

Operation: A rib resection was made under local anæsthesia, and after evacuating the cavity a subdermal infiltration was made outlining the flaps, which were dissected up and turned into the cavity. The patient showed no reaction from this operation. Twelve days later she went through a normal labour, giving birth to a healthy male child, and in three months the cavity was completely lined with a healthy skin. Six months later the cavity was completely obliterated.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

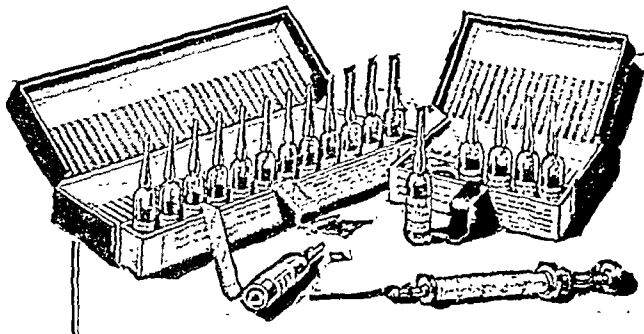
Local Sedative for Eczema

Emol-Keleet

Immediate and marked relief from the distressing itching is afforded by Emol-Keleet. Emol-Keleet is prepared from an unctuous earth. It is impalpable in texture, pleasantly sedative, emollient and mildly astringent in action, and, being purely inorganic, is available for application in purulent and inflammatory conditions.
In all dermatoses where a sedative dusting powder is indicated Emol-Keleet will be found ideal.

Samples free to the Medical Profession on request.
FASSETT & JOHNSON, LTD., 86, Clerkenwell Road, London, E.C.1.



Contramine

in the treatment of chronic infections

Practically every type of chronic gonococcal infection responds to Contramine therapy, so also do chronic cases of rheumatism, arthritis, fibrositis, and intestinal infection.

Literature and clinical reports on request

Clinical evidence shows that intramuscular injections of Contramine will often achieve results unobtainable with any other drug; moreover, the injections are non-toxic and the treatment is painless.

Issued in solution in ampoules, and in the form of pessaries.

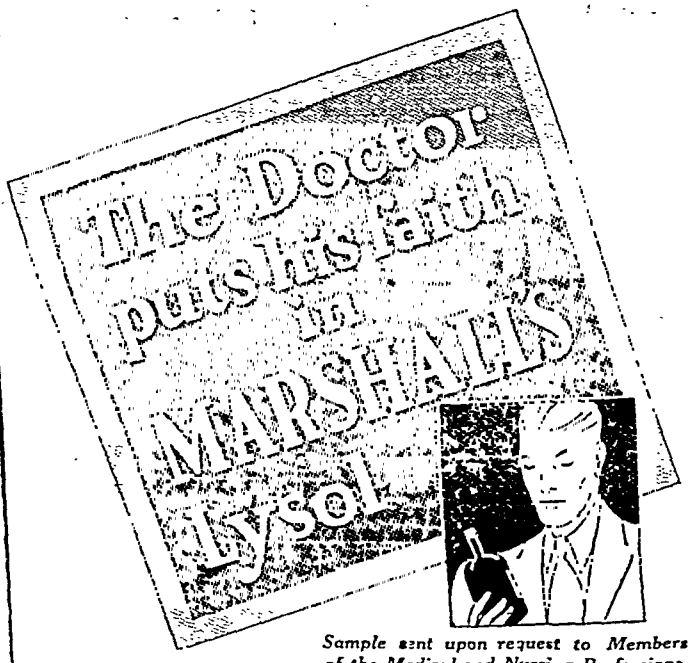
Nursing, as well as expectant mothers, need a food rich in vitamins which is easily digested and rapidly assimilated, and in the former case one which is ready to be immediately transformed into rich human milk.

Mellin's Food

containing an ample store of the vitamins essential for the nourishment of the developing babe, provides this source of energy. Prepared for use with fresh cow's milk, it combines the stimulating action of malt extractives with the high nutritive properties of fresh milk.

Samples and directions for use will be gladly forwarded by:

MELLIN'S FOOD Ltd., LONDON, S.E.15



Sample sent upon request to Members of the Medical and Nursing Professions.

IN a doctor's surgery he must risk germs of infection and contagious diseases. He must avoid carrying infection from one patient to another . . . so he disinfects his hands each time with Marshall's Lysol.

Marshall's is the only Lysol made from the original formula. A doctor who recommends it KNOWS that his patients will obtain a Lysol of unvarying strength and quality. That this is vitally important we need not stress. Every doctor and nurse knows that in midwifery, surgery, or cases of infectious disease, the highest grade antiseptic is absolutely essential.

MARSHALL'S Lysol

LYSOL LIMITED, RAYNES PARK, LONDON, S.W.20.

In General Debility

"Glycerophosphates favour the assimilation of phosphates from the food and protect the combined phosphorus of the nervous system from wasting."

Prof. A. Robin

"In Sanatogen we are offered an ideal combination to combat the wasting effect of chronic or acute illness. In fact, a better cell-reconstituent can hardly be imagined, for the casein and glycerophosphates in combination fulfil every demand for perfect nutrition."

PROF. GOLDWATER in "Therapeutic Medicine."

"I have used Sanatogen and am very pleased with the results obtained."

PROF. VON EISELSBERG of Vienna, recipient of the Lister Medal, July, 1927.

PALATABLE NOURISHMENT FOR CONVALESCENTS

It is recognised that, to be properly effective, invalid or convalescent diet must be palatable.

Marmite is a pleasantly-flavoured extract of Yeast, and rich, therefore, in Vitamin B. Being extremely palatable, it is welcomed when other foods are rejected, and has a markedly beneficial effect on the digestive system.

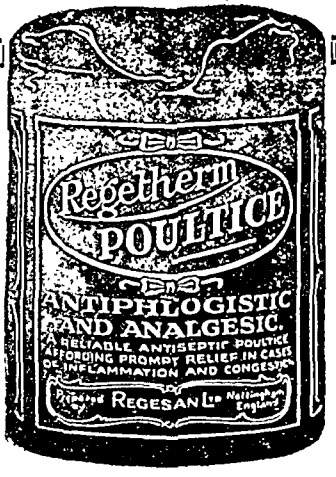
Marmite is easily administered in many ways, as a consommé made with hot water, or in a variety of invalid dishes.

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co., Ltd., 59, Eastcheap, London, E.C.3.

MARMITE

Being a Yeast Extract, Marmite supplies any deficiency of Vitamin B in the ordinary diet. It is easily administered in soups and other invalid dishes, in sandwiches, or as a consommé made with hot water.

B



REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

BOOTS PURE DRUG CO. LTD., NOTTINGHAM.

'ZYMINE' Peptonising Tubes

(FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick.

'Zymine' Peptonising Tubes have been in use since 1882, making it possible for physicians to assure proper nutrition to their patients, even in cases where digestive power has been reduced to its lowest terms, and enabling chronic dyspeptics, invalids, convalescents, etc., who must live upon fluid foods for more or less prolonged periods, to take milk in quantities sufficient to maintain nutrition and promote restoration.

Peptonised milk presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk an available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomplishes the desired purpose.

Supplied in boxes containing 6 and 12 Tubes.

The contents of one Tube will peptonise one pint of milk.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK, and 65, Holborn Viaduct, LONDON, E.C.1.

Agents:
Burroughs, Wellcome & Co.,
LONDON, SYDNEY, and CAPE TOWN.

Put your patient on

'WHITE BEAR' BRAND Cod Liver Oil

THERE is no finer grade of Norwegian Cod Liver Oil imported into this country than White Bear Brand.

It is exceptionally free from taste and odour, well-tolerated and easily assimilated. The process of refinement is scientifically controlled, hence the Vitamin activity of the oil is fully retained. Thus, the utmost benefit, obtainable from cod liver oil, is assured to the patient. The price, too, is advantageous.

TRADE MARK.

Supplied in 4 oz., 8 oz., 12 oz., 16 oz., and 20 oz. bottles by all chemists.

HIRST, BROOKE & HIRST, LTD., Leeds.

OVALTINE

FOR INSOMNIA.

Sleeplessness is a common feature of Neurasthenia. The value of "Ovaltine" in this condition is exceptional. A cup of "Ovaltine" taken upon retiring allays nervous irritability, and the patient passes into a natural and healthful sleep.

As evidence of the value of "Ovaltine" in Insomnia the following extracts from unsolicited medical reports are noteworthy:

"The patient slept the first night I used 'Ovaltine,' but I thought it merely a coincidence. By continuing its use, however, I am convinced of the value of 'Ovaltine' to induce sleep."

"In a case of Neurasthenia associated with sleeplessness and difficult feeding I gave my patient 'Ovaltine.' To my great satisfaction 'Ovaltine' was retained without difficulty, and rapid improvement followed."

"Ovaltine" is a rich concentration of the vitalizing principles of malt, milk, and eggs. Its delicious flavour and its high nutritive and digestive qualities render it a food beverage of outstanding worth.

A liberal supply for clinical trial sent free on request.

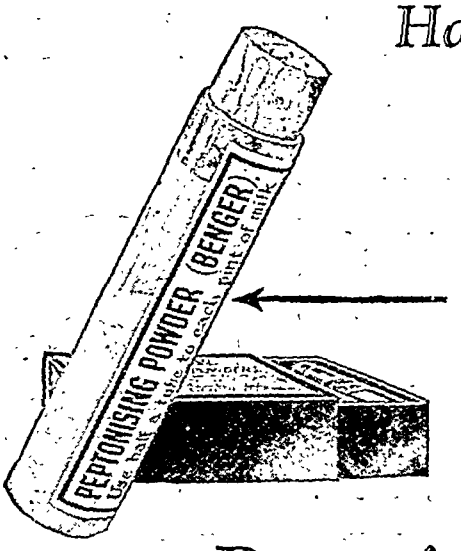
Seb-The Earth God with a figure of a goose upon his head (EGYPTIAN)

The most efficient Peptonising Powders!

Half a tube of Benger's is enough!



While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1—Box of 6, 1/-; No. 2—Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.
Prices: 3/-, 5/6 and 10/6

The Chronic

Often underlying the chronic condition is bowel stasis and irrational use of harsh cathartics.

Many chronic cases have been definitely benefited by a period of "habit time" education together with other rational treatment.

'Petrolagar' Brand Paraffin Emulsion affords a valuable aid to diet and exercise in bringing about a restoration of normal bowel movement—the effect being purely mechanical.

Petrolagar Laboratories, Limited,
Brayden Road, London, N.15.

ALTERNATIVE METHODS IN

PROPHYLAXIS & TREATMENT

OF

CORYZA

DETOXICATED ANTI-CORYZA VACCINE

This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hypersensitive patients.

ORDINARY ANTI-CORYZA VACCINE

Many practitioners consider a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of a very low price.

ANTI-CORYZA VACCINE SPRAY

(For local application to the nose and throat)

For patients who object to Vaccine treatment by subcutaneous injections, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

¶ *Practitioners desiring further information regarding the above products are invited to write for Brochure giving the full technique of use to:*

"SMILER"

INFANT MORTALITY

has been greatly reduced in this country by the replacement of liquid milk by dried milk in artificial feeding.

Cow & Gate Milk Food

Cow's Milk made safe and suitable for Baby.

The pre-eminence of 'Cow & Gate' in this respect has been testified to in a recent official investigation, as the following abstract will illustrate :—

> "*This milk is of good quality and content. It is more conveniently stored than fresh milk, and more easily preserved from contamination. Its use for artificially-fed infants has probably not only maintained and improved the general nutrition, but has also directly prevented much gastro-intestinal disease which is so often caused by impure and stale milk.*"

In the general nutrition of normal infants, as well as in the prevention of infantile gastro-intestinal disease, the unique success of 'Cow & Gate' has been attributed to the infinite care taken in the selection of the milk used, to the highly scientific control exercised throughout its manufacture, to its standardised and unvarying composition, to its high biological value, and to its bacteriological purity.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

The Standard of Purity of

INSULIN "A.B."

TRADE A B MARK **Brand**

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have never involved the slightest sacrifice of quality.

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

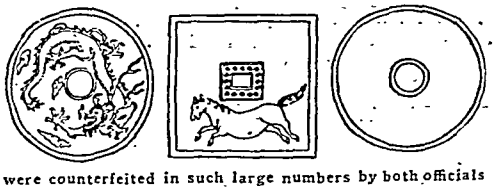
COINS OF WU TI, WHO INFLATED THE CURRENCY, IMPOSED A CAPITAL LEVY AND CHECKED PROFITEERING IN ORDER TO PROVIDE FOR THE NEEDS OF HIS PEOPLE REDUCED TO POVERTY BY COSTLY WARS, INTERNAL DEVELOPMENT AND INUNDATIONS.—The "spacious times" of the great Wu Ti, who pioneered the fortunes of China to their apogee, entailed an enormous expense which ultimately exhausted the treasury. The traders amassed enormous fortunes until Wu Ti established officials to check profiteering, to keep prices steady and to regularise them throughout the empire by controlling buying, selling and transport. Next, the traders were called upon to make a valuation of their fortunes and contribute proportionately to the state funds. Shamefully large fortunes were confiscated altogether. Wu Ti resorted also to the device of issuing coins having a nominal value far above their intrinsic worth, e.g., among those here reproduced, the "dragon" coin had a nominal value of 3000 of the former copper coins. These, however,



were counterfeited in such large numbers by both officials and people that before a year had elapsed they were no longer accepted, and the state was brought to the verge of financial ruin. To restore the currency the emperor appointed three officials who alone had the right to issue new coins. The results of these various efforts to bring back prosperity were such that: "The people enjoyed good cheer and fine clothes, and no one gave himself up any longer to increasing and accumulating his patrimony." However—"The officials, thanks to salt and iron (the chief sources of revenue) and ... the denunciation of acquired fortunes, had abundant resources."

DATE (of Wu Ti): 140-87 B.C.

Observations
ON
THE TREATMENT OF PLEURITIC EFFUSIONS.*

BY
SIR THOMAS HORDER, BT., K.C.V.O., M.D., F.R.C.P.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE choice of this subject for discussion suggests that there may be differences in the routine teaching and practice of some of us in regard to this matter, or that there may be new methods that require ventilation and criticism. In the remarks which follow I propose to deal very largely with the principles which guide me personally in practice, rather than present a summary of all the known variations upon customary procedure. It will probably be found that I have very little to say that is novel, but what I say will at any rate serve as a basis for any novelties that may follow in the course of the discussion.

I desire, in the first place, to stress the fact that the successful handling of a case of pleuritic effusion does really rest upon principles, more or less clearly definable, and that the appropriate treatment of the effusion depends upon a consideration of several factors:

1. The cause of the infection.
2. The nature of the effusion.
3. Its size.
4. The stage in the disease process at which the patient has arrived.
5. The associated condition of the lung.
6. The degree of illness of the patient.
7. The contribution made by the effusion, as such, to the illness.

The time-honoured division of effusions into serous, or sero-fibrinous, and purulent is justified both on clinical and on bacteriological grounds, and brings into close association the first and second of the above-named factors:

1. *Sero-fibrinous Effusions.*—Tuberculous; rheumatic; influenzal; lymphadenomatous; ? some other infections; neoplastic.

2. *Purulent Infections (including Empyema)*—Pneumococcal; streptococcal; staphylococcal; influenzal; mixed infections; gonococcal; coliform; streptothrix.

The stage at which the disease process has arrived when effusion is diagnosed is a fact of great importance in the decision whether to remove the fluid, and also by what method to remove it. To remove all effusions "at sight" is, undoubtedly, bad practice, and this statement applies alike to purulent as to serous effusions. Care must be taken, however, not to confuse treatment with diagnosis. It is assumed that no effort is spared to make the diagnosis as early as possible; it is also assumed that no one is ashamed of a negative pleural puncture; better a negative puncture too early than a positive puncture too late.

The associated condition of the lung should be assessed with as much care as possible. Active and acute inflammatory changes in this organ contraindicate removal of pleuritic effusion, *ceteris paribus*, and this is true whatever the nature of the infection, because the presence of the fluid is undoubtedly of conservative value in keeping the lung at rest.

But the accumulation of fluid adds toxic and mechanical factors to the patient's illness, and these must be taken into account in determining treatment of the effusion. The question often arises: To what degree is the patient handicapped by the presence of the fluid, and to what degree is he ill by virtue of his general, or his pulmonary, infection? The proper answer to this question can only be given after the exercise of judgement based upon experience.

Lastly, it is necessary to carry in mind how ill the patient is, though this has more bearing upon the manner by which the effusion is removed, and the rate at which it is removed, than upon the question whether or no it be dealt with.

These general principles will be found again and again to govern particular instances, as will now be seen.

1. SEROUS EFFUSIONS.

The great majority of these are tuberculous in origin. Their treatment follows traditional lines. If they are very large effusions they are tapped as soon as they are diagnosed. If they are associated with respiratory or cardiac distress, and this seems referable to the effusion rather than to other factors, again they are tapped as soon as diagnosed, and irrespective of their size. Thirdly, if they show no signs of (further) absorption after fourteen days or so from the date of their discovery, they are tapped. Too early an interference with serous effusions is meddlesome. There is a definite evolution in the exudative process consequent upon the disease, so that the fluid tends to collect again if removed before its high tide is reached. But a more important reason against premature removal of the fluid is that by such interference the associated collapse of the lung is interfered with, and its expansion encouraged. Should the lung itself be the seat of active tuberculous disease such expansion tends to increased activity, and if it be not itself involved its partial collapse protects it from infection from the pleura. Several days of observation of the patient are sometimes necessary in order to decide if the lung is, or is not, involved, and in cases of doubt it is better to assume that it may be. Too late an interference with a serous effusion, on the other hand, is prone to leave the lung permanently collapsed, with consequent deformity of the chest and scoliosis.

If there is evidence that the lung is diseased, and in proportion as this evidence is definite, even greater care must be exercised against too hasty removal of the liquid effusion. Our experience of the good results of collapse therapy in the treatment of some cases of pulmonary tuberculosis has an obvious bearing upon this matter. The replacement of the effusion by oxygen may be considered, and this is sometimes done with excellent results. The production of active symptoms of lung disease is not infrequently witnessed as the result of the rapid expansion which follows removal of a serous effusion when a latent focus of tubercle is present. Less often, but more serious still, a pneumothorax, with all its lamentable consequences as a complication of pulmonary tuberculosis, ensues from the same error in practice.

Whilst this policy of forbearance is in operation the doctor is not idle. The patient is, from the first, regarded as suffering from tuberculosis, and the general measures that follow upon this view are put into action. The arm on the affected side is immobilized; perhaps that side of the chest is strapped, unless it be decided to paint the skin with equal parts of the tincture and the liniment of iodine, or to apply some other form of counter-irritation. Iodides are given internally, and calcium is thought by some to be of service.

Of *auto-serotherapy* few seem to have had much experience in this country. As might be expected, the device makes considerable appeal to some French physicians, but results do not appear to be such as to call for fuller exploitation of the method. The fact is, expectant treatment of serous effusions, followed by simple removal of the liquid at a well-chosen time in those cases in which it does not undergo spontaneous absorption, is so successful that to complicate it by, or to substitute for it, other methods seems a matter of supererogation.

How to remove pleuritic effusion, when the conditions indicate this, need not be dealt with here in detail. With most practitioners the Potain type of aspirator is deservedly more popular than the method of siphonage. With the latter there is often uncertainty whether cessation in the flow is due to absence of more fluid or to blocking of the tube by clot; whereas with aspiration, provided the operation be not hurried, and the patient be made quite comfortable both in mind and in body, the risk of too rapid expansion of the lung, as shown by cough, haemoptysis, or "albuminous expectoration," is negligible. Care should be taken to see that the local anaesthesia is

* Made in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Manchester, 1929.

really effective, and there is much to say for the preliminary use of a sharp scalpel, wherewith to nick the skin, before inserting the needle attached to the aspirator. Trocars with cannulas are to be avoided, and the ritual of a major operation, which is sometimes witnessed, is quite uncalled for.

How much liquid to remove depends much upon the individual case. It is very striking sometimes to see fairly rapid absorption started by the removal of quite a small amount. On the other hand, in large effusions, there is nothing to be gained by ceasing the aspiration so long as the liquid flows easily and the patient remains comfortable.

Drugs injected into the pleura after removal of the liquid, at least on the first occasion of its removal, are of dubious value. It is a question whether they do more than satisfy an inherent weakness in human nature to complicate a simple procedure.

The after-care of the patient follows the lines indicated by the knowledge that he is almost certainly tuberculous. Therefore his convalescence must on no account be hurried. Nor must so-called "respiratory gymnastics" be brought into the scheme of treatment too soon—certainly not before the pyrexia has completely ceased, redux friction has disappeared, and any other evidence of active inflammation has subsided. Otherwise there is, once more, the danger of "lighting up" a latent lung focus or of a relapse in the acute pleurisy. A return to ordinary life must not be considered under three months from the time of cessation of symptoms, and it may be necessary to extend this period if the season of the year is unfavourable or the case has been tedious. Even then there should be rules for daily observance, as for an early case of pulmonary tuberculosis.

Rheumatic effusions are almost invariably accompanied by other expressions of rheumatic inflammation, especially by some form of carditis, and their treatment becomes part of the therapy of acute rheumatism. Aspiration is rarely necessary.

Serous effusions in influenza are either associated with active lung disease (pneumonia), when their treatment is determined by this fact and by the degree of illness of the patient; or they appear later as residual collections of fluid when the main illness has subsided, when the question should be carefully considered whether or no the effusion is not really tuberculous. These facts determine their treatment.

In lymphadenoma and in *cancer* there are no special rules of guidance: the individual case must determine treatment.

2. Purulent Effusions and Empyema.

In the main the principles governing the treatment of serous effusions operate here also. But the time factor is of greater urgency, since the old-established surgical maxim to "evacuate pus as soon as it is discovered" should not be departed from in this or in any other condition. The points under consideration, therefore, are concerned more with methods of drainage than with the time of drainage. And these methods have less uniformity in opinion and practice than is the case with serous effusions, because the conditions of satisfactory drainage of a pleural abscess are obtained with less constancy.

The various methods of drainage and subsequent treatment will now be passed in review.

Treatment by Aspiration, Repeated as Indicated.—When purulent effusion occurs during the active stage of any disease, and especially when it occurs during the active stage of pneumonia, aspiration is the method of election. Both incision and resection should be postponed, but especially resection. In not a few cases one or two aspirations suffice, and major procedures are found to be unnecessary. Not only is this so in pneumococcal cases, it is sometimes the case in septicaemia with focal pleuro-pulmonary lesions of a suppurative nature, especially when the infection is streptococcal. In influenzal cases, again, this procedure should always be given a trial before it is decided to incise the chest or to resect a rib. In staphylococcal pyaemia, on the other hand, although aspiration very occasionally succeeds, and should therefore be tried, drainage by the open method will probably be required sooner or later. Speaking generally, the more ill the patient, and the more certain the evidence of existing pneumonia, the more should the practitioner favour aspiration as against the open method. Too much care cannot be given to this consideration: is the patient ill chiefly as the result of his general infection (with or without pneumonia), or is he ill chiefly as the result of the empyema? Upon the answer to this question depends the decision to aspirate, and perhaps to repeat the aspiration, or to incise with rib resection. The course of the disease must be carefully watched if we are to arrive at the correct answer. The character of the pus is of less importance as a guide to the method to be adopted than are the above considerations. It is assumed that needles of adequate bore are used, and also of adequate length. It is sometimes difficult to persuade instrument makers that there is use for a needle which is bigger and longer than a hypodermic needle and yet smaller than a trocar.

Treatment by Simple Incision and Drainage.—This intermediate method is probably less often indicated, and less often successful, than aspiration on the one hand and resection on the other. But, again, in very ill patients this method may be resorted to with advantage, and especially when the exudate is very thick, and where there are coagula and sloughing pyogenic membrane, as in some pneumococcal cases.

Treatment by Incision (with or without Rib Resection), Irrigation, and Closure of the Wound.—This method has had a vogue of late. It is probably only applicable to pneumococcal cases, and, despite some successes, it too often transpires that recourse must be had later to the older, and more tedious, methods. Its pursuit appears to be an example of the hope that technique can, some day, triumph over experience.

Treatment by Incision, Rib Resection, and Drainage.—This is the old-fashioned method, and still remains the method of election in the majority of cases. Matters of purely surgical technique will not be entered into here. But the level of approach, so as to effect the best drainage, the choice of anaesthetic, and the extent to which digital exploration is undertaken are all of them matters which pay for careful thought. Digital exploration is probably of service in most cases: it enables the observer to glean helpful information in respect of the state of the lung, admits of the breaking down of recently formed adhesions, and facilitates the expulsion of sloughs and coagula. But forbearance should be exercised in all this: "Be bold, be bold . . . be not too bold." Modifications in the system of drainage in this, the open method of treatment, deserve further consideration and trial. The desiderata are adequate evacuation of the pus, the avoidance of more than local and temporary pneumothorax, and the least disturbance of the (presumed) diseased lung. The use of a tube which is carefully adapted to the chest wall, and which delivers into an air-tight bottle, is worth more extensive trial. Unfortunately in children, who are the very patients in whom the above-mentioned desiderata are of special importance, apparatus of a complicated pattern are difficult to keep in place.

The question of *irrigation of the empyema cavity* is one which recurs in the minds and practice of successive generations of practitioners. Whilst admitting that the calamity termed "pleural shock" is a rare event—though probably less rare in pleural lavage than in pleural puncture—it is very doubtful if irrigation as a routine procedure is justified by results. A large number of substances have been used at different times. Dakin's solution (5 per cent. neutral sodium hypochlorite) is supposed to have virtue as a decorticator and solvent as well as a germicide. Aniline dyes, such as methylene blue and gentian violet, have been used a good deal of late. Iodoform emulsion and iodized oil have their advocates. But more ambitious preparations have at times been used. One of these is pepsin with hydrochloric acid and phenol. Another is iodoform with ethyl morrhuate in olive oil. It is difficult to believe that the use of such solutions will ever get farther than the experimental stage. Two things seem clear: irrigation at the time of the operation is always of questionable value, and irriga-

tion at any time, either then or subsequently, is to be avoided if there be any suspicion of pulmonary abscess in addition to the empyema.

In *autopyotherapy* the limit of hopefulness in conservative treatment would seem to be reached; and even the recorded success in one case of injecting 1 c.cm. of the pus subcutaneously, at intervals of four or five days, seems scarcely to justify the employment of the practice as a general method of treatment.

The importance of treating the patient must never be lost sight of. Indeed, the after-care of the patient should receive special attention. Abundant aerotherapy should be adopted, and, whenever possible, the patient should be in the open air for long periods of the twenty-four hours. The diet should be simple. Sunlight or/and ultra-violet rays are often helpful. The use of vaccines, though not so popular as a decade or two ago, should be considered, and general tonic measures are not to be omitted. In this way is combated any residual *infection* that may exist, and expansion of the lung is encouraged. Respiratory gymnastics—deep breathing—may well be employed, and less caution is necessary here than in serous effusions, lest such helps be sought too early.

The problem of the residual sinuses is ofttimes a difficult one. The help of x rays and lipiodol injections is notorious. The indications for treatment when the case has arrived at this point depend upon the application of two principles: that a septic focus in the chest, however small, constitutes a general as well as a local danger; and that there are only two ways in which such a focus can be effectively dealt with—either the lung must be allowed to expand until it reaches the chest wall, or the chest wall must be allowed to fall in until it comes in contact with the lung. Which of these two modes of securing permanent healing is chosen, or whether both are chosen, depends upon the particular case. In the first instance digital exploration with efforts at decortication is the method of election; in the latter, the resection of portions of more ribs. Meantime the methods by which the patient's *general tone is re-established* must not be relaxed. In such difficulties patience, vigilance, and the pursuit of the principles stated usually achieve the end desired.

An Address
ENTITLED
LYMPH-STASIS THE PRECURSOR OF CANCER.

DELIVERED AT WELLINGTON BEFORE THE NEW ZEALAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION, FEBRUARY 19TH, 1929,

BY

W. SAMPSON HANDLEY, M.S., F.R.C.S.,

SURGEON TO THE MIDDLESEX HOSPITAL AND TO THE MIDDLESEX CANCER HOSPITAL.

(*With Special Plate.*)

I PROPOSE to use my opportunity to-day for the purpose of laying before you my views on the origin and causation of cancer. Carry your minds back, then, to the dawn of the world, uncounted millions of years ago, when life first appeared upon its surface in the form of amoeba-like organisms, each a single cell, a single unit of living protoplasm, animated by two fierce passions—the desire for food and the desire to double its ego by the simple process of cell-division.

A little later in time there arose from these unicellular organisms, organisms composed of many cells living together in a communal life like that of a small village or a great city. The cells are now specialized into groups, and each kind of cell follows a trade or profession, exerting for the community its special skill, receiving from the community in exchange food, warmth, and protection. To carry out the scheme and to ensure that each cell receives its due share of food, and of such cell products as it no longer makes for itself, elaborate systems of conduits—the circulatory, lymphatic, and glandular systems—have been evolved, and equally elaborate machinery, comparable with the telegraphs, telephones, and newspaper and business offices of the city, brings information of the outer world, and controls the activities of the cell community. As Sir Arthur Keith[1] has said: "The resemblance between the body physiological and the body politic is more than an analogy; it is a reality," and Mr. Morley Roberts[2] has insisted that politics must be regarded as a branch of the science of biology.

It is a part of the bargain that the individual cells shall abandon the primitive right to unlimited cell division. In the many-celled animals this right is reserved to the cells of the ovary and testis.

THE ORIGIN OF MANY-CELLED ORGANISMS.

It is an interesting speculation how the many-celled organisms arose from the unicellular individuals, which were presumably the first living things to appear on the globe. It appears likely that they arose from some inhibition of the process of cell division when it had proceeded half-way—that is to say, the nucleus completely divided, but the cell protoplasm still remained connected by protoplasmic strands. There is evidence that the cells of the higher animals are still interconnected by protoplasmic bridges.

To understand the origin of multicellular organisms the most hopeful avenue is a study of the processes which inhibit or frustrate cell division after the process has been initiated. Such a study might be pursued upon the amoeba.

Note that, if the foregoing sketch of evolution is true, each cell of one of the higher animals is descended from a primitive one-celled organism with an irresistible appetite for food and for multiplication. Note, further, that these are the appetites which dominate the cancer cell, and you may be led to conclude that cancer is an atavistic reversion of certain cells of the body to the state of their primitive one-celled ancestors. Such a conclusion would, in my opinion, be correct. The cancer cell is a selfish unicellular organism, derived by direct descent from the cells of the body, but living among them as a parasite.

You might further be led to compare the cancer cell, with its fierce antisocial individualism, to an anarchist in the body politic, and to inquire whether the anarchist represents a spontaneous reversion to the savage primitive type of man, or whether he is the product of disorders in the social organism. Experience shows that the anarchist does not appear, or is soon exterminated, in prosperous and happy communities. It is therefore probable that in cancer the reversion to the primitive cell type is conditioned by disordered bodily function. In other words, the body has failed to carry out the contract under which the cell abandoned its right to unlimited multiplication. Under that contract each cell of the body has the right to its share of the products of all the other cells. It has also a right to protection from external irritation. It is my object now to show how the contract has been violated. My observations lead me to believe that the origin of cancer is intimately associated with local obstruction of the lymph vessels in the area where the cancer arises. To produce cancer the obstruction must be of long standing—must have lasted from twenty to thirty years. It may not be complete enough to cause obvious lymphatic oedema, but may *manifest itself only by papillary hypertrophy* and increased cellularity of the subepithelial connective tissues.

Complete direct proof of this theory is at present impossible. But if the disconnected heap of jig-saw fragments which constitute our knowledge of cancer are tried together upon this hypothesis and are found to fit as a coherent picture, a definite orientation, hitherto lacking, will be given to experimental work on the origin of cancer. It is for the reader to judge if my work fulfils the object thus stated.

It is, I think, significant to note that the recent work of Warburg shows that the cancer cell is a cell which has somehow acquired an entirely new type of cell metabolism, but no suggestion has hitherto been offered as to the way in which this change of cell habit is brought about. It is

evident that chronic lymphatic obstruction must profoundly influence the conditions under which the cell lives. The intercellular pressure must be raised, wandering cells brought by the blood will be trapped in the district and will be unable to leave it, the supply of oxygen will be restricted, and the fluid bathing the cells will be relatively stagnant—wanting, therefore, in the supply of fresh hormones derived from other cells of the body, which it should normally contain, and wanting specially in the inhibitory hormone which is the sedative to the cell's primal passion for division.

We must now consider what light can be obtained upon the etiology of the disease from a study of experimentally produced cancer. The salient facts will be found well marshalled by P. Menetrier,[3] who has himself done so much to advance this subject. He shows that attempts to induce cancer by the injection of micro-organisms, or by the inoculation of embryonic grafts, have failed. Doubt is thus thrown upon the infective theory of cancer, and upon Cohnheim's hypothesis of its origin in embryonic "rests." On the other hand, chronic irritation in various forms has succeeded in artificially inducing cancer; and Menetrier's belief that cancer is a morbid process resulting from "multiple and non-specific forms of irritation" is thus justified. The successful irritant may be:

1. A physical agent, such as *x* rays, radium, or heat.
2. A chemical agent, such as tar or paraffin.
3. A parasitic agent, such as the spiroptera which causes stomach cancer in rats, and possibly the bilharzia (bladder cancer) and the demodex (Borrel).

It must be observed in passing that it does not take us far to say that chronic irritants produce cancer. We want to know whether their effect is a direct one on the epithelium, or is exerted indirectly through an action upon the connective tissue. If the latter, what is the nature of the connective tissue change?

To resume our study of Menetrier. By exposing the ears of guinea-pigs for long periods to repeated small doses of *x* rays he produced hyperplasia of the epithelium and metaplastic alterations of the cells. He draws attention to the great thickening of the epithelium, and to the formation in it of cell nests, also to "papillomatous appearances," which he evidently considers deceptive and due to the downgrowth of epithelial processes, a mistake which Clunet also made. He does not refer to the changes in the connective tissue of the papillae.

In concentrating his attention upon the epidermic changes and ignoring those in the connective tissue, I believe that Menetrier has missed the true interpretation of his results.

In his figure (Fig. 9) there are to be seen hypertrophied papillae, a stage of real if incipient papillomatosis. In the centre of each of the two hypertrophied papillae on the left are seen cellular cords, uniting below to form a single vessel. My experience with lupus (cf. Fig. 7) warrants me in asserting that these cords are papillary lymphatics of origin in a state of proliferative lymphangitis. In the papillae to the right of the figure the process has gone further: the vessels have been destroyed and a richly cellular mass of granulation tissue has replaced them (cf. Fig. 8). In my view, then, the *x* rays have set up an obliterative lymphangitis of which the epithelial hypertrophy is a secondary consequence. A direct stimulating action of the *x* rays upon the epithelium may no doubt occur, but it is of less moment than the lymphangitis which Menetrier ignores, as will be seen when the facts of lupus carcinoma are studied.

Marie, Clunet, and Lapointe exposed a number of white rats to a few successive massive doses of *x* rays, each dose causing a severe dermatitis. In two cases a spindle-celled sarcoma arose in the irradiated area, but epithelioma was not produced in any of the animals. These experiments, from my point of view, show the predominance of the connective tissue changes produced by chronic radiation over the epithelial changes. Though in man the epithelial changes may ultimately prove of more serious import, they are conditioned by previous long-standing chronic lymphangitis, and perhaps to a less extent by obliterative haemangeitis.

It may be remarked that papillomatous hyperplasia is a recognized precursory stage of *x*-ray cancer. Furthermore, early *x*-ray epitheliomata have a tendency to remain localized for a long time, and only disseminate when they have advanced by infiltration into regions where the lymphatics are still intact. In these respects they resemble lupus cancer, which is certainly conditioned by lymphatic obstruction.

In 1923 Block succeeded for the first time in producing an *x*-ray carcinoma in a rabbit.

TAR CANCER.

The precancerous stage of clinical tar cancer manifests itself by the production of warts (Fig. 11), which mostly after a time drop off, leaving an erythematous or pigmented patch. Sooner or later one of the warts grows, becomes broad-based, ulcerates, and develops all the signs of malignancy (Fig. 12). Yamagiwa and Ichikawa in 1914 first succeeded in producing experimental tar cancer by painting the ears of rabbits with coal-tar once every two or three days. Sometimes the applications were preceded by the intradermic injection of scarlet-red, an admirable means of irritating the lymphatic vessels. In from 30 to 100 days papillomatous new formations appeared. In certain cases after 55 to 360 days carcinoma appeared. In a later series of experiments carcinoma was produced in 77 per cent. of the experimental animals. In 72 per cent. metastases occurred. The same authors injected tar into the mammary gland of female rats, and produced cancer of the mamma in 12 per cent. of the animals. Yamagiwa and Ichikawa state that "repeated simple chemical and physical irritation renders the normal epithelial cell cancerous, without any necessity to invoke another unknown causal agent." This statement requires examination. It is at least possible that the tar acts primarily upon the connective tissues, and we must now inquire into the evidence available upon this point.

It is certain, at any rate, that the connective tissue is not indifferent to the irritation of tar, for in Fibiger and Bang's experience, out of 24 tar carcinomas in mice, 2 were accompanied by a tar sarcoma. Russell produced sarcomas by deep or subcutaneous injections of tar.

More direct evidence of the importance of the connective tissue changes produced by tar painting comes from Borrel. He noted the accumulation of connective tissue cells (mastocytes) forming little intra-epidermic or sub-epidermic collections. Prolongations from these mastocytes insinuate themselves between the cells of the Malpighian layer, which is thus dissociated. The observations of Borrel harmonize with those of Victor Bonney,[4] who in every case found that the origin of a cancer is preceded by increased cellularity of the subjacent connective tissue. Menetrier, without, I think, sufficient reason, ascribes these collections of connective tissue cells rather to accidental infections of the skin than to the action of the tar. Nevertheless, Menetrier himself, in the epithelial hypertrophy of the hair follicles, which is one of the precursory stages of tar carcinoma, observed a great increase in the number of branched pigmented connective tissue cells (chromatophores) lying among the deeper layers of the epithelium and in the superficial layer of the dermis. Evidently in such cases a powerful stimulus has been applied to the connective tissue.

In the other precancerous stage of tar carcinoma, that of papillomatous hypertrophy, the deeper layer of the epithelium shows a hyperplasia of the chromatophores (pigment-bearing connective tissue cells) which it normally contains. Later an increase of chromatophores is seen also in the underlying dermis.

It must, however, be admitted, as Menetrier insists, that in the rabbit's ear the onset of tar carcinoma may occur in the absence of any connective tissue proliferation. It is true, as Menetrier says, that this fact runs contrary to the views of Ribbert as to the importance of inflammation of the connective tissues in the origin of cancer, but, on the whole, the balance of evidence points strongly to the view that the action of tar is primarily upon the connective tissue. I suggest that tar produces cancer by causing lymphatic obstruction with papillary hypertrophy as an intermediate stage in the process.

It has long been known that the evolution of a papilloma into a carcinoma is not a rare event, but the closeness of

FIG. 1.—Cross-sections of skin papillae in Paget's disease of the nipple, showing blocked central lymphatics.

FIG. 2.—Cross-sections of skin papillae in lupus, showing blocked central lymphatics. (*Cf. Fig. 1.*)

FIG. 3.—An innocent duct papilloma of the breast. (Contrast Fig. 4.)

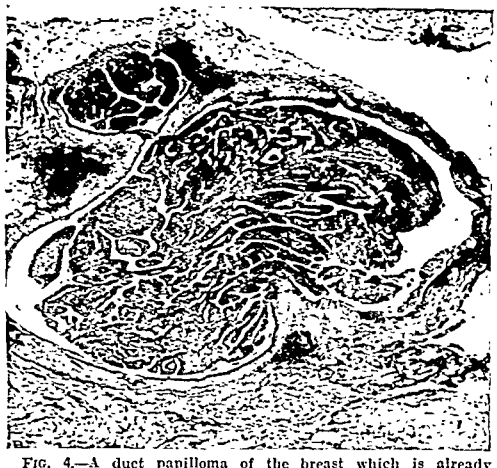

FIG. 4.—A duct papilloma of the breast which is already carcinomatous. (Contrast Fig. 3.)

FIG. 5.—A highly magnified portion of the papilloma seen in Fig. 4, showing infiltration of its connective tissue by malignant epithelium.

FIG. 6.—Hypertrophied papillae adjacent to a carcinoma of the tongue. On the right the edge of the carcinoma is seen.

FIG. 7.—Section just beyond the edge of an area of non-ulcerative lupus of the skin, showing the blocked papillary lymphatics which simulate a stag's antler in outline.

FIG. 8.—A much hypertrophied papilla of the skin in lupus occupied by tuberculous granulation tissue and by a line of giant cells representing the original central lymphatic.

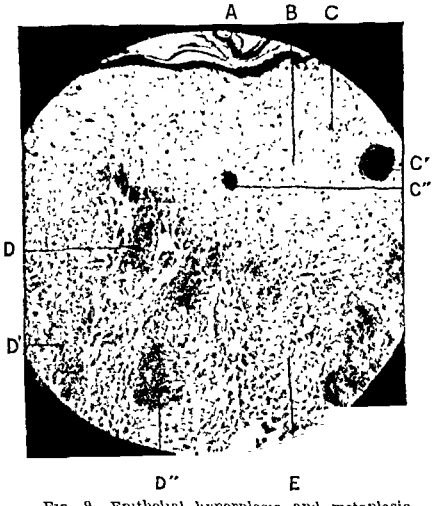

FIG. 9.—Epithelial hyperplasia and metaplasia in the ear of a rat following x-radiation. From Menetrier, *Le Cancer, Généralités*, p. 129.

FIG. 10.—Lupus carcinoma of the left cheek. On the right cheek is seen an innocent papilloma.

FIG. 11.—Tar warts of the forearm. From a patient who had worked in hot tar for twenty years.

FIG. 12.—The scrotum of the same patient, showing a tar carcinoma.

the relationship between these two forms of tumour has only very recently been realized. It seems probable that carcinoma is invariably preceded either by a definite papilloma or by a local area of papillary hypertrophy.

Chronic glossitis with papillary hypertrophy is the usual precursor of carcinoma of the tongue (Fig. 6). Cancer of the lip and of the larynx frequently arises on a pre-existing papilloma. In regard to carcinoma of the stomach there is no evidence.

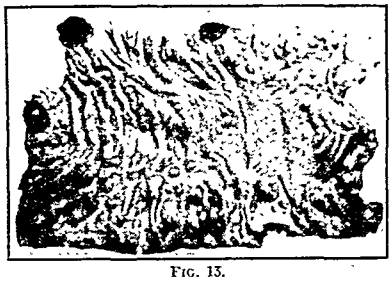

FIG. 13.

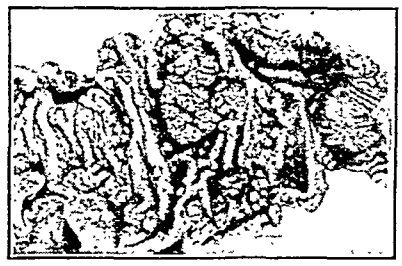

FIG. 13A.

FIG. 13.—Portion of colon removed by operation from a case of multiple adenomata. Note the little round tumours scattered over the mucous membrane. (M.A. 5.) (× 3.) (Dukes.)
FIG. 13A.—To show the naked-eye appearance of the simple tumours associated with a cancer of the rectum. (Dukes.)

Cuthbert Dukes[5] has shown that in the neighbourhood of early carcinoma of the large bowel groups of papillomata can be usually demonstrated, though these disappear at a later stage (Fig. 13A). He infers that carcinoma of the bowel begins as a papilloma. Cases of multiple papillomata of the colon are known to end almost invariably in carcinoma, and generally before middle age is reached (Fig. 14). Dukes has been able to demonstrate the origin of carcinoma at the tip of a papilloma (Fig. 15). On two occasions I have seen a papilloma appear at the lip of a colostomy opening as a little stalked, perfectly innocent, tumour, and develop within a few weeks into a carcinoma. On the first occasion, in a case of abdomino-perineal excision of the rectum for carcinoma, the new primary carcinoma grew rapidly and produced a malignant stricture of the colostomy opening. On the second occasion I excised the incipient carcinoma with scissors. It was the earliest and smallest carcinoma I have seen, and resembled Fig. 14.

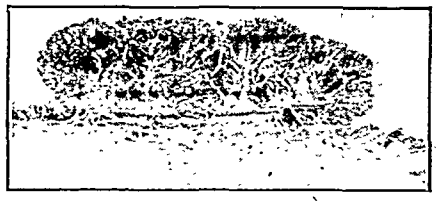

FIG. 14.—A complete section through a very early cancer of the rectum, which measured only 1 cm. in its broadest diameter and projected like a little button about 3 mm. above the surface of the bowel. Four small non-pedunculated adenomata were found within a radius of two inches of the growth. (M.A. 6) (× 8.) (Dukes.)

MULTIPLE PAPILLOMATA OF THE LARGE BOWEL.

Jüngling[6] has supplied a remarkable family tree covering *four generations* descended from a male who died of pulmonary tubercle and a female who died of old age. Both the ancestors were free of polyposis. Of their thirty-one descendants, fourteen suffered from polyposis of the alimentary tract, five from cancer of the rectum. Two of the first generation died of intestinal tubercle. Four of the six children of the first generation died of carcinoma of the rectum. For further details the family tree must be consulted. It appears to justify Jüngling's assertion that the tendency to polyposis behaves as a Mendelian dominant.

Professor Jüngling makes no comment on the fact that this family had a tuberculous ancestor and that tubercle reappeared in the two succeeding generations. Yet it seems to me likely that this fact is the key to the unknown pathogenesis of intestinal polyposis. It is known that when tubercle attacks the skin it may cause either an ulcerative or a warty non-ulcerative form of lupus. I believe that when it attacks the mucosa of the intestine, and fails to produce ulceration, an intestinal polyposis is the result. And just as carcinoma may attack the scarred area of a lupus, so may it arise in an intestinal polyposis. Papilloma of the bladder likewise, in my opinion, is a non-ulcerative form of tubercle of the bladder. A case in which I removed a typical polypus from near the right ureter, and had subsequently to remove the right kidney for what proved to be advanced tubercle, remains in my mind as a probable indicator of the pathogenesis of vesical polypus.

It might appear useless to bring forward these hypotheses upon such inadequate evidence. I do so in order to suggest that some young investigator who reads these lines should endeavour to produce intestinal and vesical polypus in animals by injecting the lymphatics locally with a suspension of active tubercle bacilli.

CANCER OF THE BREAST.

In the case of the breast the appearance which Lenthal Cheatle calls the "laciform edge" is a diffuse papillomatosis of the smaller ducts. He points to this appearance as a precursor of malignancy. If, as Cheatle maintains, and I think correctly, nearly every case of breast carcinoma originates in the ducts, it is probable that nearly every case of breast cancer is preceded by papillary hypertrophy or by definite papillomata.

Duct papilloma of the breast is recognized clinically when it arises in the larger ducts and causes serous or blood-stained discharge from the nipple. Such cases, if neglected, are known to end usually in carcinoma. In the following case I was able to demonstrate the occurrence of carcinomatous degeneration in a duct papilloma of the breast, which had apparently only existed for a very short time. At the time of the operation the papilloma was suffering from carcinoma, but the disease had not yet attacked the tissues of the patient herself.

FIG. 15.

FIG. 15A.

FIG. 15.—A polypoid adenoma situated close to a large ulcerating cancer of the rectum, but separated from it by an inch of normal mucous membrane. Other smaller adenomata were also present. The cells at the tip of this tumour had undergone cancerous degeneration (A) (see Fig. 15A); B, lymphoid follicle in stalk of tumour (dark mass). (M.A. 9.) (× 6.) (Dukes.)
FIG. 15A.—A higher magnification of the tip of the polypoid adenoma illustrated in Fig. 15, to show onset of cancer at tip. (× 135.)

Mrs. ——, aged 70, noticed a serous discharge from the left nipple a week before she was first seen on June 12th, 1928. The breast was normal on palpation except that, vertically half an inch below the left nipple, a tiny very superficial shot-like swelling could be

felt. Pressure at this point made fluid exude from the nipple. No other nipple changes were found. There were no glands in the axilla. On June 15th, 1928, this lump was cut down upon, two dilated ducts were exposed, divided close to the nipple surface, and then again divided where they began to ramify in the breast substance. On section of the excised portion across the ducts a small papilloma, just visible to the naked eye and perhaps one-fiftieth of an inch in diameter, was found within the duct, attached to it by a slender pedicle. A section across the tissue showed that this minute and early morphological papilloma had already become a carcinoma within its own substance. The fibrous tissue of its core was infiltrated with carcinoma cells, though there was no evidence that the physiological tissues of the patient had been attacked by the disease. The pedicle of the papilloma, fortunately included in the section, was composed of fibrous tissue only, and showed no infiltration. (Figs. 4 and 5.)

An indication of the pathogenesis of the papilloma was, however, given upon examination of the pedicle. It showed several cylindrical groups of round-celled infiltration, some cut as circles, others as ovals. In company with one of the groups was a small artery. These are exactly the appearances given by blocked lymphatics which have lost their lumen by proliferation of their endothelium, as I know from my experience of lupus and elephantiasis. In other words, the patient had suffered from a chronic lymphangitis of the tissues of the breast, and it appears highly probable that the resulting lymph-stasis was one of the main exciting causes of the papilloma which so rapidly developed into a potential carcinoma. It appears possible that the *Demodex folliculorum*, known by the work of Dr. Helen Chambers and others to be so common an inhabitant of the nipple and of the terminations of its ducts, is competent to excite mild infections and abrasions of the nipple, which, while causing no clinical symptoms, may nevertheless set up a chronic lymphangitis.

By this time you will, I think, admit that a process of papillary hypertrophy, sometimes only to be shown microscopically but often producing visible warts or papillomata, is the characteristic precursory stage of carcinoma. Chronic irritation, whether it be bacterial or chemical, would appear to be a cause of cancer, because it is a cause of papillary hypertrophy. If this be so, a study of the origin of a papilloma may be the key, and at least must be an essential preliminary to an understanding of the genesis of carcinoma.

THE PATHOGENESIS OF THE PAPILLOMA.

If a single papilla of the skin or of a mucous membrane is examined it is found to consist of a teat-like elevation of the connective tissue carrying in its substance a mesh-work of blood capillaries. These capillaries are supplied by an arteriole and drained by a venule. The papilla is clothed by a covering of epithelium, and it has always been presumed by the dermatologists that the active agent in the formation of a papilloma is increased proliferative activity on the part of the epithelium, and that the increase in size of the connective tissue papilla is merely a response to increased nutritive demands from the active epithelium. Unna, on these grounds, objected to the word "papilloma," and wanted to substitute for it the word "acanthoma," as indicating an innocent tumour of the prickle epithelium. He ignored an essential anatomical element of the papilla which is the key to its normal and morbid physiology. The central structure of every papilla of the skin or the mucous membrane is a lymphatic capillary exactly like the lacteal vessel of a papilla of the small intestine. I have demonstrated this by direct lymphatic injections of the skin, as well as by a study of diseases affecting the skin lymphatics (Figs. 1 and 2). Papillary hypertrophy occurs, and I believe only occurs, when this central lymphatic vessel of the papilla is blocked. The papilla is a little physiological engine. From its blood capillaries there exudes into its connective tissue spaces a constant nutritive stream of diluted blood plasma at a certain pressure. The excess of fluid is renewed and the equilibrium maintained by the drainage action of the central lymphatic. Block this lymphatic and what will happen? The first effect will be a rise in the pressure in the intercellular spaces of the papilla, and on ordinary hydraulic principles the papilla will increase in size until the intercellular pressure is equal to the pressure in the capillary blood vessels. A second effect will be over-nutrition and consequent proliferation of the papilla itself and of the overlying epithelium. But the most important effect of all for our present purpose remains to be considered. In the normal papilla a constant stream of blood fluid, along with lymphocytes, is exuding from the capillaries and passing away by the lymphatic. As soon as the lymphatic is blocked, stasis occurs and the flow of fresh blood fluid through the papilla is arrested or greatly retarded, even though just as much blood may be passing through its blood capillaries. Two consequences are inevitable: the supply of oxygen to the tissues of the papilla, to its epithelium as well as to its connective tissue, will be much reduced; furthermore, the supply of hormones to the cells of the papilla will be cut off or greatly diminished. In this connexion I use the term "hormone" perhaps somewhat loosely, to signify those products of the rest of the cells of the body which are necessary to the well-being of the cells of the papilla we are considering. Here, I think, we approach the crux of the problem.

Local lymphatic stasis brings about a definite rupture of the contract in virtue of which the unicellular organism originally forsw ze its egotism and became a social unit. Or, in the terms of biochemistry, the epithelium covering the papilla is deprived of the supply of growth-inhibiting substance, which in a well-conducted cell community is circulated to every cell.

I have shown that local lymphatic obstruction must seriously reduce the supply of oxygen to the epithelium of the blocked papilla. It would not be surprising if, in the course of years, the affected epithelium, adapting itself to meet this difficulty, should acquire a type of metabolism in which oxygenation played a relatively subordinate part. Warburg has recently brought forward strong evidence that the carcinoma cell, as compared with the normal epithelial cell, is an anaerobe, deriving most of its energy from the hydrolysis of sugar into lactic acid, and relatively little from oxidation. This remarkable fact is in exact accord with the theory of the origin of cancer which I am presenting to you. It must not be forgotten that in dealing with such a complex matter as the origin of cancer, direct proof is, in the earlier stages, not to be expected. All that can be hoped is to fit together the isolated facts into a coherent pattern.

In only one variety of cancer can I present with absolute clearness to you all the stages from the initial obstruction to fully developed carcinoma, a cycle of changes occupying in the human subject from twenty to thirty years. Tuberculous lupus, especially of the non-ulcerative variety known as lupus erythematosus, is followed, in a certain proportion of cases, by the appearance of warts upon the scarred surface, and one or more of these warts may develop into carcinoma (Fig. 10). Lupus carcinoma has been stated to be an *x*-ray carcinoma, and it may have become more frequent since the discovery of *x* rays, but it was quite common before *x* rays were known, and it is a natural evolution of the disease process known as lupus. By the examination of sections at and just outside the growing edge of areas of non-ulcerative lupus, I have been able to show[8] that the disease is essentially an obliterative tuberculous lymphangitis which destroys the lymphatics (Figs. 7 and 8). The characteristic lupus nodules found in the dermis are produced by proliferation of the endothelium of the affected lymphatics. The earliest stage of the lymphangitis is seen in apparently normal skin outside the visible edge of the diseased area (Fig. 7), and here also papillary hypertrophy of the diseased papillae can be seen. Passing back to the centre of the area of lupus, progressive enlargement of the papillae up to five times their normal length can be seen. Here, then, it is evident that blocking of the lymphatic is the primary factor, with chronic papillary hypertrophy as its consequence. The further development of the papillary areas into carcinoma is a matter of common clinical knowledge. If tubercle affecting the skin may cause papillary hypertrophy, may produce definite papillomata, and may ultimately give rise to cancer, it would seem likely that tubercle in other parts of the body may have the same result. It is perhaps significant that the form of lupus which most commonly produces cancer is the non-ulcerative or papillary form in which there is lymphatic obstruction without ulceration or destruction of tissue. This fact lends colour to my suggestion that multiple papillomatosis

of the large intestine, and also papillomata of the bladder, are really products of abortive local tuberculous infection occurring in early life.

In this connexion I would draw your attention to some very interesting observations by Dr. Thomas Cherry[7] of Melbourne. He ascertained statistically that whereas during the last thirty years the death rate from tuberculosis has greatly diminished and that from cancer has greatly increased, the combined death rate from tubercle and cancer together has remained at a constant level. This curious fact, though susceptible of several interpretations, in his opinion indicates that persons who recover from an attack of tubercle are likely in later life, and as a consequence of their attack of tubercle, to die of cancer. Since every tuberculous infection is of the nature of a chronic lymphangitis, and must leave behind it some degree of lymphatic obstruction, Dr. Cherry's facts, derived from the whole mortality experience of England over a long series of years, offer rather a startling suggestion of the importance of tubercle, and hence of lymphatic obstruction, in the etiology of cancer. Early this year Dr. Cherry published in the *Medical Journal of Australia* a paper in which he records that, by the subcuticular injection of active tubercle bacilli in mice, he has been able to raise the incidence of malignant tumours to a significant extent in the mice experimented on. These experiments call for repetition and confirmation. It is certain that under modern conditions an abortive attack of tubercle is a common event of early life. The frequency of healed scars at the pulmonary apices and of tuberculous tonsils and adenoids suffices to prove this. May not mild, undetected tuberculous infection of the mammary glands in childhood leave behind it areas of lymph-stasis which give rise in middle life to duct papillomata and carcinoma of the breast?

Where I would differ from Dr. Cherry is in denying to the tubercle bacillus any specific role in the production of cancer. In my opinion any pathological process which gives rise to lymphatic obstruction may be a cause of cancer. The specific factor is not the particular organism concerned, but the lymphatic obstruction to which that organism may give rise.

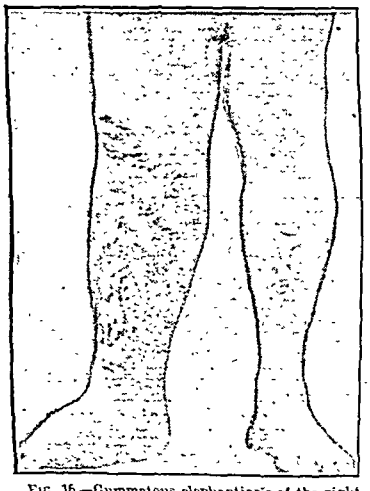

FIG. 16.—Gummatous elephantiasis of the right leg. From a case seen with the late Dr. J. J. Pringle.

The tubercle bacillus is not the only organism which finds itself at home in the sluggish stream and quiet backwaters of the lymphatic vessels. The history of syphilis is mainly a study in the pathology of chronic lymphangitis. The primary lesion is a local proliferative lymphangitis. There follows enlargement of the regional lymph glands, and then an invasion of the great fascial lymphatic plexus with an accompanying secondary rash, often presenting papillary lesions. The mucous membrane where it joins the skin is next invaded, and here lymphatic obstruction is clearly evidenced by the appearance of condylomata, mucous patches, and moist papillomata of the tongue and lips. Then, in the tertiary stage, the deeper lymphatics are invaded, and gummata, which are areas of local proliferative lymphangitis, make their appearance (Fig. 16). The chronic glossitis which syphilis leaves behind it is an obstructive lymphangitis, known frequently to lead to papillary hypertrophy and carcinoma. Carcinoma of the lip and of the inside of the cheek frequently arises on the scar of an old mucous tubercle.

Chronic lymphangitis is not exclusively caused by the organisms of tubercle and syphilis. It may be due to many other organisms—for instance, to the members of the pyogenic group—and these organisms, also, in so far as they may produce lymphatic obstruction, are potential cancer-producing agents. Chronic lymphangitis may also be set up by a chemical or thermal agency. I have already given prima facie reasons for thinking that tar cancer, and the kangri cancer of Kashmir, and the epithelioma which occurs on the scars of old burns, are caused in this way. The fact that spontaneous tar cancer in man is usually preceded for years by the appearance of crops of warts which drop off, leaving a pigmented area, is presumptive evidence of the coexistence of a chronic lymphangitis, and the initial lesion of the tar carcinoma of mice is usually a papilloma.

Papillary hypertrophy as a consequence of pure lymphatic obstruction, apart from local infection, is perhaps best seen in elephantiasis. I have also produced it experimentally in the ear of the rabbit by placing an elastic ligature, not so tightly as to strangulate the blood vessels, round the base of the ear. Warts not rarely occur upon prolapsed rectal mucosa, and may become malignant (Fig. 17).

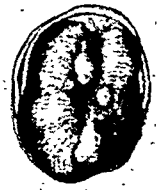

FIG. 17.—Prolapse of rectum with polypi.

Is there any connexion between elephantiasis and carcinoma? If my contentions are correct, there ought to be. Well, I would point out that the chronic ulcers of the legs so often seen in elephantiasis may become malignant. A more striking example of the connexion is within my experience. A lady who had lived in India for many years came home with typical elephantiasis of one leg. She was persuaded by a friend's advice to try radiant heat baths for the leg, and shortly afterwards virulent multiple epitheliomata, twenty or thirty in number, appeared on the skin of the affected leg. The regional glands became enlarged and she died in a few months.

In this case, judging by the multiplicity and activity of the growths, the cancerogenous factors were very active. The diseased leg differed from the healthy one in two obvious respects: it was the seat of long-standing lymphatic obstruction, and its surface when in this condition had been subjected to irritation by heat and light.

In this address I have dealt with a great subject, and necessarily, in the present state of knowledge, my remarks contain a large element of speculation, though for the sake of brevity and emphasis I have put them in dogmatic form. I shall be content if you admit my proofs that lymph-stasis lies at the root of cancer—certainly of carcinoma, possibly of sarcoma. For the rest, my address is a working hypothesis, which may perhaps serve to orientate the work of younger men.

The anatomist, the physiologist, and the biochemist, and I would add the physician, have devoted too little attention to the lymphatic system. The biologist has never attempted to produce from a unicellular organism a bicellular one, still less a multicellular one. There exists, I believe, a four-celled organism, two of whose cells only possess mouths. Here in embryo is the multicellular animal. I challenge the biologists to produce experimentally a two- or four-celled organism from a unicellular one. When this has been accomplished, the converse problem, that of the origin of cancer, may prove easy of solution.

In conclusion, I do not want a tombstone, but neither am I content to lie under the green turf of oblivion. I would like to be remembered for two things: first, as having shown twenty-five years ago that cancer spreads mainly by lymphatic permeation; and secondly, as having demonstrated to-day the importance of lymph-stasis in its etiology.

CHRONIC DYSPEPSIA IN CHILDREN OF SCHOOL AGE.*

BY

F. S. LANGMEAD, M.D., F.R.C.P.,
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON.

The Usual Clinical Features.

The term "chronic dyspepsia" in children is used to connote a group of symptoms, varying in degree and in proportion, which together form a common clinical picture. For the most part it arouses no memory of exact morbid anatomy or of precise deviations from the normal in functional activity. The picture presented to our minds is somewhat as follows. The child is ailing, dull, and listless, lacking vitality and composure. The appetite is poor and capricious, the tongue coated, and the breath heavy and perhaps foul. The complexion is muddy, while the facies, with sunken eyes, or puffy eyelids and dark orbital rings, is itself characteristic enough to suggest the nature of the malady. There may be *abdominal pains* of varying degrees of severity, from slight discomfort to attacks of colic; or pain may be absent. The pain may occur after food, but is seldom gastric in position, being more often about the umbilicus or along the course of the large intestine. It may be related to the passage of flatus or precede defaecation. The *general nutrition* is usually impaired, the child losing weight in severer forms, failing to gain weight in milder. On the other hand, the weight may be satisfactory but there is a general toneless ness of skin and muscles. The *stools* are variable, in some cases infrequent, in others too frequent, but always irregular. They may be uneven in their consistence, particoloured, offensive, and contain mucus or even blood, and food which has not been digested. There may be slight nocturnal *fever*, perhaps with bouts of higher fever, coincidently with which the odour of the breath and the abdominal symptoms become more evident. *Sleep* is restless, often disturbed by dreams or night terrors. In some cases there is wakefulness. In the morning the child is tired and drowsy, and dislikes getting up. During the day he is easily exhausted and fatigued, liable to headaches, and lacks concentration or interest in his school work, being slow in acquisition and poor in performance. *Psychical symptoms* take an important place, but are more prominent in some cases than in others, depending in their degree, in part at least, on hereditary psychical traits. The child is apt to be morose, despondent, resistant, and irritable, solitary in habit, taking no part in games, and subject to fits of crying and of temper. Examination of the abdomen may reveal no abnormal physical signs, or there may be some persistent or intermittent abdominal distension, related chiefly to flatulent distension, but in some cases in part to faecal accumulation. There may be considerable indicanuria.

Some Comparisons with Adult Dyspepsia.

When we scrutinize this motley collection of symptoms, which together we are accustomed to call "dyspepsia," we realize that they do not differ materially from those of many adult dyspeptic patients. It is customary to contrast the symptoms in adults and in children, but the difference lies chiefly, I think, in the relative infrequency of organic lesions in children, and not in any great divergence of symptoms in what is called functional dyspepsia at the two ages. There is a similar condition of the skin, of the tongue, and of the breath, and similar varying tumescence of the abdomen. Flatulence, anorexia, irregular colicky pains, irregular undigested motions, nutritional disturbance, morbid and uncontrolled mental states, are common to both, and differ in the main from those of adults only in a manner or direction which might be expected.

There appears to be a growing tendency to regard this common form of dyspepsia in children, called intestinal dyspepsia, as a disorder apart, contrasting etiologically as well as symptomatically with dyspepsia in adults. It may be doubted whether this attitude is justified, if functional dyspepsia be considered alone and organic lesions, such as septic or alcoholic gastritis, gastric and duodenal ulcerations, or gastric or intestinal new growths, be ruled out of the argument.

It must be granted, however, that the form of dyspepsia known as gastric, in contradistinction to intestinal dyspepsia, is less prevalent in children than in adults. Pain after food, when it occurs, is more often situated about the umbilicus than in the epigastrium, hypochondrium, or back. Return of food and eructation of flatus are less usual, the sensation of distension, eerie sensations of detachment, so-called gastric angina, and cardiac phenomena such as palpitation and tachycardia are not so often met with. There is not, moreover, the ordered relation of pain to food which often pertains to dyspepsia in adults.

Although it be granted that dyspepsia with prominent gastric symptoms is relatively rare, and dyspepsia with intestinal symptoms relatively frequent in children, we are not justified in the present stage of our knowledge in disregarding the stomach in the common dyspepsia of childhood which we call intestinal and assuming that it plays no part. Our information on functional disorders of the stomach and intestine is less precise in children than in adults, and we cannot with an equal degree of assurance correlate symptoms and signs with defects in secretory, motor, or sensory function.

Etiology of Intestinal Dyspepsia.

Analysis of the symptoms shows that they fall into three groups—abdominal, constitutional, and psychical. The etiological relationship between these groups has provoked some discussion. Does the intestinal dyspepsia, by leading to the absorption of poisons, cause the constitutional disturbance and the functional nervous phenomena, or is there some underlying cause responsible for all three groups? The former view is that generally held, and was supported in a recent discussion by Reginald Miller. H. C. Cameron, on the other hand, is of opinion that there is an antecedent acidosis, as shown by lowered alkalinity of the blood, and that this is responsible for the nervous and also the intestinal symptoms. The question is full of difficulty and cannot be settled without fuller knowledge. The whole position of toxaemia, arising in that home of lost causes the intestinal tract, is thorny and contentious. In attempting to solve the problem we should not, I hold, forget that there are many cases of dyspepsia in adults which are essentially the same as the intestinal dyspepsia of children. Nor should we overlook the commonplace knowledge that any disorder which causes loss of restful sleep and exhaustion will lead to fretfulness, resistance, apathy, and eventually to moroseness in a child, as in an adult, but that in a child they are likely to be more in evidence, being less controlled. Neither toxaemia nor acidosis need be invoked to explain defective nutrition in a child with chronic digestive disorder. No useful purpose would be served by my pursuing the argument further, for I believe that much more work is necessary before the question can be answered with conviction.

I propose to approach the etiology of dyspepsia in children from a different point of view and consider some of the clinical antecedents which appear to me to have an important bearing upon it.

1. *Dietetic Causes.*

Whether we regard it as the primary or merely as a contributory cause, food plays an important role. Some cases are associated with continued overfeeding; others with meals so frequent or irregular that appetite is absent. Frequently the sequence of events is as follows: appetite is lost from overfeeding, then tit-bits are given between meals to tempt it because the usual meals are not taken, until a coated tongue, listlessness, and the other attributes of dyspepsia follow. The failure to gain weight, or its loss, is followed by insistence upon still more food, with perhaps the addition of cod-liver oil until further dyspepsia and wasting occur. A child will always take its food if there is appetite, and there is no surer way to court dyspepsia than to [illegible]

*The opening paper of a discussion in the Section of Diseases of Children of the Annual Meeting of the British Medical Association at Manchester, 1929.

reluctant and resistant child, forgetting Macbeth's grace, "Now good digestion wait on appetite, and health on both!" Not infrequently I have been told by mothers that the dyspeptic child will not take its food except by the encouragement of a stick. The physiological importance of appetite is, of course, one of the ascertained truths of digestion. Among other means by which we find it destroyed is the giving of cod-liver oil, or chocolate, or other fatty foods, a short time *before meals*.

Another common error is the giving of food *at or near bedtime*, which leads to restless sleep, with dreams or night-terrors, to tiredness and headache in the morning, and to an antipathy to breakfast. The child then goes empty to school or with a stomach filled by food taken in the absence of appetite. *Food bolting* in excitable children, to whom meals are so much loss of time from games, or in children with ravenous appetites, brings its own train of dyspeptic symptoms. The meal is begun eagerly, but after a few mouthfuls have been hurriedly swallowed appetite ceases, there is abdominal uneasiness, perhaps definite colic, and that symptom popularly known as "stitch," accompanied by flatulence. This last symptom is one which should always arouse inquiry into the rate of feeding rather than into the particular ingredients of the food.

A diet containing too much "*roughage*," as it has been called—one leaving too large and coarse a residue—is an important factor in many cases, and one which, I think, is especially related to those with signs of mild colitis, in which mucus and occasionally blood is passed in the stools. It is a subject for argument whether the colitis is caused by the mechanical action of the undigested particles or whether these are detrimental to a colitis produced in other ways—for example, by bacterial causes. In this regard I would suggest that the finding of a particular substance in the stools is no certain proof that it is the primary cause. All those who eat nuts or strawberries, or jams with pips or seeds, or similar substances, will pass recognizable detritus in the stools, but most people do so with impunity and without dyspepsia. Too much stress, therefore, should not be laid upon the etiological significance of any undigested particles found in the faeces. They indicate what the child has been taking, and perhaps taking in excess, but they do not necessarily indicate the actual cause of the indigestion. Whether, however, they are the initial cause of the disorder, or whether they contribute to its persistence or its severity, there can be little doubt that such mechanical irritants are of moment and should be taboo when there is evidence of disturbance of the large intestine. Among the commoner irritants of this kind are nuts, especially the hard and resistant and altogether indigestible variety found in cakes and sweets (such as nut-milk chocolate), coarse oatmeal, and certain *proprietary cereal foods*, *unripe fruits* such as apples, and the artificially matured banana, excess of which is a prevalent abuse. On numerous occasions pieces or strings of undigested banana covered with blood-stained mucus have been presented to me by the mothers of dyspeptic children, either as curious objects found in the stools or under the guise of worms. A chemical irritant producing colitis is *liquid paraffin*, often administered too plentifully and too persistently for constipation.

Relative excess of one of the elementary food factors is apt to be less considered in children of school age than in infants, but there is no doubt that faults in dieting are often committed along these lines. There is in children of this age, as in infants, much variation in ability to digest carbohydrates and fats, so that carbohydate and fat dyspepsia are more readily provoked in some than in others. Defective powers of digestion for either is often accompanied by distaste for the food which cannot be readily digested. This is especially noticeable in the case of *fat dyspepsia*, and there are many Jack Spratts among children who will eat no fat voluntarily. If made to do so they suffer from dyspepsia. The stools in such cases are pale, greasy, rancid in odour in those more severe, but may be misleading in appearance, and in spite of a brown colour may contain much excess of fat. The severest cases of fat dyspepsia do not survive to school age.

The fermentation, which arises from *carbohydate excess*, leads to the stools being voided forcibly with flatus. They are acid in reaction, sometimes sufficiently so to produce soreness of the anus, are often accompanied by mucus, may be partly or wholly fluid, and if formed are ragged and pitted by the gas evolved. The habit of eating biscuits and sweets at night on going to bed is a common cause of such evacuations in the morning. *Protein dyspepsia* of a chronic kind is to me, at any rate, somewhat ill defined and uncertain.

Protein Sensitization.—There is, however, a group of cases, with dyspeptic symptoms, which arise from protein sensitization. This disorder should be borne in mind when nausea and vomiting repeatedly follow rapidly upon the taking of food, in the absence of acute illness, or other ready explanation. It has already been stated that these symptoms are unusual in the ordinary chronic dyspepsia of childhood. Inquiry may elicit that the vomiting is always after a particular article of food, such as fish or eggs or apples, and their omission brings the attacks of vomiting to an end. Other signs of protein sensitization, such as asthma or urticaria, may exist in the same children and may be found to occur after the vomiting attacks. In a recent case an apple always produced vomiting, to be followed by urticaria, and withdrawal of this "apple a day" sufficed to prevent any recurrence of the attacks.

It may be doubted whether *vitamin deficiency* takes any part in the dyspepsia at school age, but the possible relationship of atony and dilatation of the stomach and intestine to deficiency of vitamin B requires further elucidation.

Defective mastication is another cause which must be considered, and in this respect the state of the teeth and gums is of some importance. Any mechanical defect due to an imperfect bite or to tender teeth or gums is, however, relatively slight, in my view, in comparison with the infection which accompanies these conditions. The need for laborious and painstaking mastication has probably been exaggerated; Mr. Warwick James tells me that observation of school children has shown that the strong and healthy ate their meals rapidly with a minimum of mastication, while the weakly took much longer over them. This observation is open to other interpretations, for it is possible that the weakly child, although taking more time, may not actually chew more effectively, and poor appetite may provide less saliva to mix with the food.

The state of general health and vigour is of first-rate importance, for while a strong open-air country child may eat raw turnips and *unripe apples voraciously without* harm, one feebler and more sheltered may suffer after indiscretions more venial.

2. *The Role of Infection.*

If we turn from diet as a factor to infections we enter upon more uncertain ground. There are certainly some few cases of entero-colitis where are encountered specific organisms such as those of dysentery, to which the symptoms should rightly be ascribed. There are also a few cases in which lamblia is probably the pathogenic agent. In a considerable number *Streptococcus*, generally *viridans*, less often *haemolyticus*, is preponderant in the stools over *Bacillus coli communis*; sometimes haemolytic coliforms are found in large numbers; sometimes other organisms—for example, the bacillus of epidemic jaundice—are found. It is not possible, however, to correlate the symptoms and course of the digestive disorder with the infection, either in degree or kind, nor can it be claimed with certainty, except in the case of dysenteric infections, and perhaps in that of lamblia, that the departure from the usual intestinal flora is primary and provocative and not merely secondary and incidental.

A difficult question, and one worthy of discussion, is the manner of production of the toxaemia. Is it to be explained by infection by pathogenic organisms of the intestine, by excessive formation of toxins due to abnormal digestive processes and the abundance of suitable pabulum for the ordinary flora of the gut, by increased permeability of the mucosa, or by weakness in protective power? Stasis alone does not seem to me to be an adequate explanation, for it is not a prominent feature in the dyspepsia of children, and the severest degrees of toxaemia often coincide with loose, frequent, and bulky motions.

F. Power and C. Sherwin have isolated the main non-nitrogenous and nitrogenous products of the action of bacteria upon the proteins of the intestine, and found that they had to give more than 50 mg. of indole or skatole to produce symptoms in man comparable to those of constipation. They suggest that the intestinal mucosa itself is an important detoxicator of putrefactive products, and that the body possesses a chemical defence mechanism more than adequate for the detoxication of putrefactive substances normally produced by the action of bacteria upon unabsorbed protein material in the intestine. It has often been shown that indicanuria is no guide to intestinal putrefaction. J. Olivet recently corroborated this, and demonstrated that there is no parallel between the amount of indicanuria and the degree of decomposition in the bowel, while in complete paralytic ileus indican is often absent from the urine. These observations seem to rule out stasis and putrefaction as sources of the intoxication, at least as long as the mucosa is healthy.

Whatever the relation between the intestinal flora and the dyspepsia or its toxic symptoms may be there are certainly cases of this disorder which only improve after treatment of focal sepsis. Dental sepsis, unhealthy tonsils and adenoids, and sepsis of the nose and accessory sinuses are not uncommon in dyspeptic children; when these have been satisfactorily dealt with the abatement of the dyspepsia is often manifest.

The frequency of the appendix as a source of infection and cause of intestinal dyspepsia is probably not great in children, but this is again a matter on which opinions differ. The issue is somewhat confused by the similarity between the symptoms caused by chronic appendicitis and tuberculous glands in the right iliac fossa. In a case which was under my care chronic appendicitis appeared to be the cause of pyloric spasm and secondary gastric dilatation. It was that of a girl aged 10, who suffered from repeated vomiting. There was a large area of gastric tympany with splashing several hours after food, and *x*-ray examinations proved the existence of dilatation and a varying degree of delay at the pylorus. During her stay in hospital she developed an attack of acute appendicitis. After removal of the appendix, which showed evidence of earlier inflammation as well as of the acute attack, the vomiting and delay at the pylorus ceased, and ultimately the signs of gastric dilatation disappeared. Gastric delay and dilatation with splashing under examination is an occasional occurrence at this age, but I have had no further opportunity of demonstrating any relation between it and chronic appendicitis. I believe that in children, as in adults, there are examples of dilated and splashing stomachs due to excessive ingestion of fluids.

3. *Hepatic Dyspepsia.*

Dyspepsia in children has been divided for descriptive purposes into gastric, intestinal, and hepatic forms. In this paper I have dwelt chiefly on the usual intestinal form, and have pointed out that the variety in which gastric symptoms predominate is relatively uncommon. The cases which I have been accustomed to call "hepatic" have been those in which fats are badly borne, in which there are from time to time bouts of toxaemia, with pale greasy stools, slight jaundice, and sometimes a palpable liver. Defective functioning of the liver may, however, be a factor in many of the cases and may be related to the toxic symptoms. Liver function tests, at best somewhat unreliable, are rendered still more so by intestinal disorder. In that unexplained malady, *coeliac disease*, in which disordered fat metabolism is coupled with such lack of development that the term "intestinal infantilism" came to be applied to it, and in which the mental features are so characteristic, the liver may play an important part. The use of bile salts certainly increases the power of these children to deal with fats.

In *cyclical vomiting* the extreme fatty change found in the liver in the fatal cases is the most noteworthy post-mortem appearance, and the close resemblance of the severe cases to those of delayed anaesthetic poisoning seems definitely to inculpate the liver. Whether this organ is primarily at fault, or whether it is damaged by toxins derived from the bowel, is a moot point. The bouts of toxaemia, accompanied by acetonaemia and the presence of the acetone series in the urine, are not wholly explained by "ketosis"; they differ from diabetic coma and are little influenced by alkalis. There is also a well-defined group of cases in which periods of toxaemia occur, with a strong odour of acetone in the breath, and in which acetone and diacetic acid are found in the urine. These appear to resemble cyclical vomiting in every particular, except that vomiting is absent; perhaps they should also be included among the hepatic dyspepsias. Mellanby holds that the outpouring of bile salts into the duodenum is of vital importance in digestion, and that it is the bile salts and not the gastric hydrochloric acid or other substance which leads to the liberation and absorption of secretin, upon which depends the secretion of the pancreatic juice. This mechanism depends very largely upon the *p*H values in the duodenum, and this to a large extent upon the gastric activity. This view throws the essential upset to digestion upon impaired bile flow rather than upon alterations in gastric secretion, for without the presence of bile salts in the duodenum the pancreatic ferments are not produced except by a nervous mechanism. This work must be borne in mind when attempting to estimate the position of the liver in cases of dyspepsia.

4. *The Role of the Nervous System.*

Mention has already been made of the frequency of nervous symptoms in the disorder under discussion. They loom large in many of the cases and perhaps reach their acme in coeliac disease. Are they the result or the cause of intestinal symptoms in the usual intestinal dyspepsia, or are both due to some antecedent cause, such as the acidosis described by Cameron? In this connexion the high values of the fat in the blood found by Monerieff and Payne in coeliac disease may be of importance in indicating a primary dysfunctioning of the nervous or chemical regulators of fat metabolism.

I should be glad to hear the opinions of others on this subject; my inclination is in favour of the nervous symptoms being secondary in most cases to the intestinal disorder, partly due to toxins, partly to loss of restful sleep, partly to the effect of exhaustion. Many of these children, however, are of the nervous type originally, though made worse by the dyspepsia and by the solicitude and petting of anxious parents.

There are a few examples of disordered action of the alimentary tract in children to which the name "nervous" may properly be applied in an etiological sense. Among them is that much-debated group in which there is *disordered neuro-muscular co-ordination*, leading to local spasm or failure of dilatation of segments of the tract—for example, at the cardiac end of the oesophagus, at the pylorus and in the colon, producing dilatation and hypertrophy above the situation of the zone of constriction. In another group there is *depression or exaggeration of the gastro-colic reflex*, dyspeptic symptoms in the former case being consequent upon constipation. When the gastro-colic reflex is exaggerated, intake of food is promptly followed by colic, or, in less severe cases, by discomfort about the umbilicus and along the colon, and a hurried evacuation of the bowel—the lienteric diarrhoea of the older writers. Again, *excitement or anxiety* in nervous children, as in adults, may lead to failure of the normal reaction to the taste and smell of food and complete abeyance of appetite. Lastly must be mentioned among the dyspepsias primarily nervous that which—accompanied by colitis—is consequent upon the neurosis known as *pica* or dirt-eating.

Summary.

After describing the symptoms of dyspepsia in children of school age as it is usually met with, and making a brief comparison between it and dyspepsia in adults, it is suggested that there is no fundamental difference between intestinal dyspepsia in children and many examples of dyspepsia in adults, and no reason for regarding it as a disease apart, with an individual etiology. Some views as to the interrelation of the various symptoms have been mentioned, but it has been held that our present knowledge is not sufficiently exact to argue this question with precision. The relations of dyspepsia at this age to diet, to local infections, to the liver, and to the nervous system have then been considered briefly.

MINOR INJURIES TO THE EYE IN INDUSTRY.*

BY

BERNARD CRIDLAND, F.R.C.S.Ed., D.O.Oxon.,

SENIOR HONORARY SURGEON, WOLVERHAMPTON AND MIDLAND COUNTIES EYE HOSPITAL.

Eye injuries in industry have received from time to time a good deal of attention, but it has been mainly towards the major ones involving loss of one or both eyes that interest has been chiefly directed. This is as it should be, for industrial eye injuries are by no means the least important cause of blindness. Thus in the report of the Departmental Committee on the Causes and Prevention of Blindness it is stated that 10 per cent. of the blindness in three of the largest cities in the country was due to accident; sixteen other causes were mentioned, but only three of these were responsible for a higher percentage, and only one of the three (ophthalmia neonatorum) to any appreciable extent. Moreover, from various reasons the figure 10 per cent. is, I think, rather lower than it should be.

Again, in the report of the Departmental Committee on the Welfare of the Blind, published in 1917, Professor Collis states that *5 per cent. of all accidents reported by* certifying surgeons—that is, all accidents in industry—for the years 1907 to 1914 were eye accidents, and that of these at least 2.5 per cent. resulted in the loss of one or both eyes. In the departmental report of the Scottish Register of the Blind 7.2 per cent. are stated to be due to occupation.

And next, if we turn to American statistics, which cannot be far different from our own, we find that accident *is responsible for 13.5 per cent. of all blindness in the* United States. Furthermore, out of 250,000 eye accidents which occur annually in the United States, there was loss of, or serious impairment of, vision in one eye in 3,100 cases, whilst there are no fewer than a hundred cases of total blindness in industry every year in that country.

A very full survey of eye accidents in industry was made some years ago by the Departmental Committee appointed by the Ministry of Health to investigate the causes and prevention of blindness generally. The report was published in 1922, and you are no doubt familiar with the excellent recommendations which were made with regard to prevention. The statistics made use of by the committee were based wholly upon major accidents—that is, cases which had required admission to hospital and were in receipt of compensation—but no reference was made to the minor injuries beyond the remark in one paragraph that "there are also many minor eye accidents causing absence of less than seven days and which are not reported."

It is to these minor injuries that I wish especially to draw attention, for, so far as I am aware up to the present time, there is little information as to their economic effect in industry—as to what they mean both to employer and to employed, as to how far they are worth preventing, and, if so, what more can be done in the way of prevention. No doubt some attempts have been made, but that much still remains to be done will at once be acknowledged by all surgeons of eye hospitals and departments, especially those situated in industrial areas, where a good proportion of all the cases seen are accident cases of major or minor type.

In my own hospital of fifty beds 6,880 accidents were dealt with in 1928, as compared with 6,040 other new cases due to disease or requiring refraction—a proportion of 53 per cent. In the past twenty years there has been an increase in this proportion from 39 per cent. in 1909 to the 53 per cent. already mentioned for 1928. The vast majority of these accidents *are of course minor ones*, and it is fortunate that only a very small proportion involve the loss of one or both eyes. I find that the giant magnet was only used in twelve cases in 1928.

Recently the Council of British Ophthalmologists appointed a subcommittee to ascertain what effect had been given to the recommendations of the Departmental Committee on the Causes and Prevention of Blindness in its report of 1922. In the course of its investigation the subcommittee thought that it would be of value to obtain accurate reports of minor eye injuries, involving less disablement than a week, from the casualty and out-patient records of hospitals situated in representative industrial areas. Accordingly a special case-card was designed in which the following essentials could be recorded—namely, *the occurrence of the accident, its effect as regards time* lost and injury (permanent or otherwise) sustained, and any details as to the adoption of prevention. These case-cards were distributed, and information on 426 cases was obtained from four surgeons—namely, Mr. J. Jameson Evans of Birmingham, Mr. A. J. Ballantyne of Glasgow, Mr. R. J. Coulter of Newport, and myself. The number obtained was not a large one, but the investigation was in the nature of a trial trip, and it was intended that if useful information was revealed the matter would be pursued further on similar lines. I am indebted to the Council of British Ophthalmologists for permission to bring forward the details of a review of this work, which are as follows.

Taking the cases first of all from the point of view of occupation, it was possible to divide them into three main groups:

A. Regular or occasional workers at grindstones or emery wheels, involving exposure to small flying particles	51%
B. Occupations involving exposure to chips of metal	26%
C. Miscellaneous	23%

In Group A the risk of serious injury is small, the lesion almost always being a foreign body on the cornea. In Group B the risk of serious injury is greater. Group C includes a variety of occupations—from miners, road workers, painters, and plasterers, to general labourers. The injury is usually an odd one—from a simple foreign body on the cornea, a burn or contusion, to lime in the eye.

Types of Injury.

	Per cent.
Foreign bodies on the cornea	90
Abrasions of the cornea	5
Miscellaneous (burns of lids, wounds of the conjunctiva, contusions of the globe)	5

Information as to Protection (406 Cases).

	Per cent.
A. Protection not used	70
B. Protection admitted available but not used	19
C. Protection made use of (chiefly goggles, otherwise machine guards)	11

Time Lost from Work owing to the Accident (three Groups).

	Cases.
A. Those who lost from 1 to 2 hours (comprising all where it is presumed the workman was able to return to work at once)	371
B. Those who lost from 2 to 8 hours	48
C. Those who lost from 8 to 24 hours	7

At a rough average estimate the time lost from work is 992 hours, or 124 working days of eight hours each, due to 426 cases of minor eye injuries—that is, seven minor eye injuries mean the loss of two days of eight hours each. This is undoubtedly a low estimate, as, from information received through welfare supervisors, many men do not return to work that day, whilst those who do frequently waste much more than two hours.

Other factors which must also be considered as causing loss of time are the covering with pad and bandage of the injured eye, which is done in many hospitals, and which, even if the man returns at once to his work, proves a great handicap. As a rule, however, a bandaged eye means no work for that day. The instillation of atropine, which is sometimes *thought necessary, acts in a similar* manner, and is a handicap for days, even though the eye is uncovered. And, again, a man is frequently told to attend the hospital the next day for observation.

These are factors which add materially to the loss of time away from work and which have not been taken into account in computing the foregoing figures. It would, in fact, seem a fair and reasonable estimate to say that every three minor eye injuries mean one whole day's loss

*A paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Manchester, 1929.

of output. In a small percentage of cases no working time is lost, as the man struggles on with his work until closing time, attends the hospital, and recovers by the next day, to return at the usual time.

The following table shows the time which elapsed between the occurrence of the accident and the attendance at the hospital (information obtained in 234 cases).

A. Cases which attended at once	5
B. Cases which attended after 1 to 12 hours	119
C. Cases which attended after 12 to 24 hours	65
D. Cases which attended after 2 to 6 days	45

The average time which elapsed between the accident and the attendance at the hospital was sixteen hours per person. These figures are of value from the point of view of the increased liability to infection owing to delay.

Some information was also obtained from the records of a firm employing 975 hands (males 675, females 300), taken over a period of nine months. Of these, 98 cases of minor eye injuries were reported at the well-equipped first-aid station, 85 of which were dealt with by the nurse, the remaining 13 being sent to the Wolverhampton Eye Infirmary. Of these 13 cases, the amount of time lost from work averaged about two and a half hours each in 12 cases; the thirteenth, more serious, lost about twenty hours (or two and a half working days). The total loss of time due to the 13 cases of minor eye injury amounted to fifty-eight and a half hours—nearly one and a third working weeks. The injuries comprised in these 98 cases were:

Foreign bodies	48
Dust or sand in the eye	27
Blows with chips of metal	14
Burns with hot metal or acid	9
	98

The monthly incidence of the cases was as follows: January 10, February 7, March 9, April 14, May 12, June 11, July 8, August 12, September 15. The monthly incidence was taken in order to see the effect of hot weather, meaning fatigue. Apparently the figures show nothing in this respect from which to draw any conclusion. This is in contradistinction to the finding of Lafon of Périgueux, who in 1911 made elaborate statistics of 2,816 cases of foreign body on the cornea incurred in various industries, which presented themselves at the Bordeaux Clinic between 1896 and 1906. His conclusions were as follows:

1. The number of cases increases with the hours of work, the maximum being reached at the end of the day. The increase is proportional to the development of fatigue.

2. The number increases towards the end of the week in proportion after the Sunday rest.

3. The number increases with the elevation of the temperature, which diminishes the resistance to fatigue.

4. The number is inversely proportional to the age of the patients—the younger the worker the more easily is he fatigued and the greater the incidence.

Thus fatigue, both mental and physical, is the explanation of the variations shown by the statistics, and he suggests that, besides suitable protection, some rest, especially in the hot months, should be allowed.

These observations, though based on a comparatively small number of cases, are sufficient to show that from the economic point of view minor eye injuries are of considerable importance. Further, it must be remembered that from sepsis any minor injury may become a major one—as, for example, when a pneumococcal ulcer of the cornea follows an abrasion incurred in coal mining or the heavy iron trades.

As has already been shown, the large majority of minor eye injuries are caused by flying particles, and it naturally follows that there are two ways in which the prevention of such injuries can be achieved: (1) to ensure that the flying particle does not reach the eye, and (2) better still, to eliminate the flying particle altogether. It is on these two essentials that the three main principles of prevention are based. They are as follows: (1) mechanical guarding; (2) education of workmen and foremen; (3) engineering revision.

1. *Mechanical Guarding.*

Mechanical guarding is the interposition of a guard between the eye and the flying particle. It comprises various forms of goggles, machine-guards, and shields, face-masks, and helmets or hoods, according to the area of the head and neck it is desired to protect. For the protection of the eyes themselves it is a question of goggles and shields, either held in the hand or fixed to the machine. Goggles, if of the right kind and properly worn and kept in order, form 100 per cent. protection, as against 90 per cent. offered by shields; but, on the other hand, it must be borne in mind that the goggle at its best is a handicap to output of work, and that the shield is more likely to be in its place than the goggle. If an ideal pair of goggles could be produced and put on the market at a reasonable price it should not be so difficult a matter to induce men to adopt the fashion of wearing them. The words "adopt the fashion" are purposely used, for fashion is the prelude to custom. The chief difficulty lies in producing the ideal goggles. Such might be visualized as being an instrument a man could wear all his working day, hardly realizing that he was doing so, and at the same time without impeding his output in any way.

Out of the many models that have been devised one of the most acceptable, referred to by the Chief Inspector of Factories and Workshops in his report for 1927, has been adopted by the Shipbuilding and Engineering Trades Mutual Assurance Association. No doubt many present are familiar with this model, which consists of a strong frame with flexible ear-catches containing lenses of fair size made of toughened glass. There are no side flanges, and ventilation can take place freely, so that the lens surfaces are not dimmed by moisture. Messrs. Hamblin's Limited have produced a model on these lines fitted either with toughened glass or "splintanil," a material which on receiving a sharp blow behaves in the manner usual to all types of safety glass.

An ingenious form of protection of quite another type is one which consists of a piece of silk gauze, and which, I understand, is very effective in stopping small flying particles from emery wheels, etc., but gives little protection in the heavier metal industries. Yet another type is one modelled (at the suggestion of Mr. Treacher Collins) on the visor invented by Sir Richard Cruise in the late war. This visor of fine chain mail attached to the steel helmet was allowed to hang in front of the eyes, and formed from experiment a good protection against splinters of all kinds, at the same time causing little interference with vision. I think, however, that it would be difficult to get men to take kindly to wearing this model.

2. *Education of Workmen and Foremen.*

This, the second principle of prevention, is one which naturally is directly associated with the first, and simply means making the man realize the risk he is running and teaching *him* how best to avoid the danger.

3. *Engineering Révision.*

The third principle is the most recent method of prevention, and as amongst other things it seeks to eliminate the flying particle altogether, it is the ideal. It aims at doing away with the underlying cause of accidents rather than the covering up of danger points. The term is generally understood to mean the changing of a manufacturing process, the re-designing of a machine or tool, the rearranging of the physical equipment of a plant, or the changing of the method of work to any other for the purpose of preventing accidents. The introduction of the automatic machine is an excellent example of engineering revision, since fewer men are required for the same amount of work, and therefore fewer are exposed to hazards.

One cannot help feeling that it is by engineering revision we are likely to meet with the greatest success in prevention, for we *are* then independent of the necessity of guards and education of workmen. The last-named method seems to be very difficult to carry out in this country—more perhaps than in others. In America, for example, a

fair amount of success has been met with by the employment of safety engineers, who, in addition to concentrating on engineering revision, make a special point of educating the workmen by propaganda and many ingenious and telling methods. If it was possible to ensure that all of the three methods could be carried out simultaneously, it could be imagined that all accidents due to flying particles would be abolished. In theory no accident ought to occur, but actually it is impossible to prevent those due to unforeseen circumstances.

The prevention of eye accidents in the great variety of occupations followed in this country is, on investigation, a much greater subject than might be thought, and it is impossible in a short paper such as this to enter into the detailed study which is necessary for each type of occupation, but it is hoped that enough evidence has been brought forward to show that minor eye injuries have an appreciable importance in industry.

The fact that *three* of such simple everyday occurrences as a foreign body on the cornea are responsible for the loss of a whole working day of eight hours should be sufficient to arouse the financial attention of every employer, quite apart from the suffering borne by the employee. Furthermore, when, in addition, the burden on the hospitals is taken into account, it must be conceded that the time is ripe for some great effort to be undertaken towards the reduction of these apparently trivial accidents. The word elimination would, of course, be preferable to reduction, but this would involve superhuman efforts.

The difficulties in the way are great, and not the least among them is the psychology of the employee, especially when of British nationality. No disparagement of my countryman is here insinuated, but merely a reference to the wonderful spirit of indifference to danger so characteristic of our race, to which may perhaps be added some ignorance of risks run.

THE RESULTS OF INDUCTION OF LABOUR WITH ANIMAL BLADDERS.

BY

G. F. GIBBERD, M.S., F.R.C.S.,

OBSTETRIC REGISTRAR, GUY'S HOSPITAL.

In 1901 Baumm[1] described the method of induction of labour in which a sterile animal bladder is introduced through the cervical canal, and then partially filled with glycerin. As a semi-permeable membrane the bladder allows water to pass from the surrounding tissues into its cavity, so that its contents gradually increase and the bladder becomes progressively more distended. At the same time a small proportion of the glycerin passes out into direct contact with the uterine wall.

Although the method seems to have been fairly widely used on the Continent, it has attracted little attention in this country, and the figures published here represent the results obtained in the first thirty cases in which the method was tried at Guy's Hospital. I am indebted to the obstetric surgeons at that hospital for permission to publish these results.

The technique used has been modified slightly from that suggested by Baumm. The apparatus that has been found most satisfactory consists of a short piece of metal tube about one inch long to which is attached a piece of rubber tubing about six inches in length. Through this a long metal stylet is passed so that its point projects about five inches beyond the end of the metal tube. The end of the stylet is flexible, and protected at the tip by a smooth knob. The animal bladders, which are obtainable ready sterilized in sealed glass tubes, are of two sizes—a large (pig's) bladder with a capacity of about 500 c.cm., and a small (sheep's) bladder with a capacity of about 200 c.cm. The bladder is tied to the metal tube by means of a silk ligature, and stretched by means of the stylet. It can thus be introduced through the cervical canal in the same way as a Krause's bougie, and when it is completely within the uterine cavity the stylet is withdrawn, and (in the case of a large bladder) about 200 c.cm. of pure sterile glycerin is injected into the bladder by means of a syringe. The rubber tubing is then clamped. The flexible stylet ensures deflection of the bladder, should it hit against the presenting part, and thus renders the introduction a simple and safe procedure. With care the bladder can be introduced without coming into contact with the skin of the vulva or vagina, and without any undue handling on the part of the operator, but the aseptic technique practically always makes an anaesthetic necessary.

After introduction into the uterus the contents of the bladder gradually increase in amount; at the same time a small amount of glycerin passes out into direct contact with the uterine wall. The uterus is thus subjected to the double stimulus of the mildly irritating glycerin and of the gradually increasing size of the bladder. In the later months of pregnancy a large bladder has been used in the majority of cases. The smaller bladder is more suitable for the induction of abortion in the early months.

In the majority of the cases previous unsuccessful attempts to induce labour with quinine and pituitary extract had been made. Several cases in which abortion was successfully induced in the early months of pregnancy have been excluded. Only cases in which pregnancy had progressed past the twenty-eighth week are considered here. The indications for induction in these cases were either disproportion between the size of the head and the pelvis, or maternal toxaemia. It is not suggested that the results obtained are to be regarded as entirely satisfactory, but for the purpose of comparison they are considered side by side with the results of twenty-three consecutive inductions with bougies or stomach tube, undertaken at Guy's Hospital during the same period and under similar conditions.

Results.

	Animal Bladder.	Stomach Tube or Bougie.
Failures	3 (10%)	2 (9%)
Successes	27 (90%)	21 (91%)
Induction interval:		
Longest	72 hours	95 hours
Shortest	2 hours	2 hours
Average	13 hours	35 hours
Less than 24 hours	25 (83%)	8 (40%)
Less than 12 hours	17 (63%)	4 (20%)
Less than 6 hours	11 (41%)	2 (10%)
Puerperal morbidity	4 (15%)	3 (14%)
Complications:		
Separation of placenta	1	1
Malpresentation	1	Nil

The three cases in which the method failed may be considered separately. In the first, a patient with albuminuria of pregnancy, since no pains had occurred eighty-eight hours after the bladder had been introduced, this was removed and a stomach tube was inserted instead, after which a further thirty-eight hours elapsed before the onset of labour. The puerperium was morbid on account of pyelitis. In the second, a patient with a contracted pelvis, labour pains started and the bladder was expelled after forty-eight hours. After this the pains ceased entirely, and pregnancy then ran a normal course until it was terminated by Caesarean section ten days later. In the third patient the bladder was expelled with a few pains, which ceased almost immediately afterwards. The patient refused any further intervention and was discharged from hospital. She was admitted in labour four weeks later, and delivered with difficulty, by the forceps, of a dead foetus, death being due to intracranial haemorrhage. A normal puerperium followed.

Although all three cases must be regarded as complete failures in that the object of the operation was not attained, yet it is satisfactory that the attempt did not

influence unfavourably the results of subsequent treatment. Of course, the fact that a foreign body has been introduced into the uterus must add considerably to the risks of sepsis if further intervention is necessary subsequently, but in the three cases in this series this danger was fortunately not manifest.

The twenty-seven cases in which the method succeeded will next be considered. The chief advantage of the method lies in the comparatively short time in which labour started in the majority of cases. The "induction interval"—that is, the interval between the introduction of the bladder and the onset of pains—is often of considerable importance. In pre-eclamptic patients it may be a matter of urgency that labour should start within a few hours. In all cases an interval of more than thirty-six hours is, at least, a cause for some anxiety. The comparative figures which have been quoted amply justify the conclusion that the induction interval with animal bladders is very much shorter than with the stomach tube or bougies.

Quite apart from the question of efficacy in inducing labour, certain dangers associated with the method must be considered. The injection of large amounts of glycerin between the membranes and the uterine wall is said to be followed by alarming toxic symptoms. In the method here described only a small amount of glycerin can pass out of the bladder, and that very slowly. Nothing suggestive of a toxic effect has been noted in any case in this series.

The presence of any foreign body in the lower segment must tend to displace the head from the pelvic cavity. With animal bladders displacement of the head was noted several times, and on one occasion it caused a breech presentation with a prolapsed cord. The child suffered no harm, but this fortunate result does not, of course, lessen the seriousness of the condition, which must in this case be attributed to the method used. The only other accident which occurred was separation of the placenta in one case. Since the bladder and stylet are passed for a distance of about five inches into the uterus, it is evident that this accident may occur if the placental edge is less than five inches from the internal os. It would probably be sufficient to rupture the membranes and reinsert the bladder within the amniotic cavity in such an emergency; but in the case in which it did happen a smaller (sheep's) bladder was inserted, and no further haemorrhage occurred.

In four cases the puerperium was morbid (British Medical Association standard), but in one of these the rise in temperature was considered to be due to a urinary infection, and in another to an attack of influenza. In the other two cases there was evidence of uterine sepsis of a mild type. The danger of sepsis must exist whenever a foreign body has been introduced into the uterus, but this danger will be minimized in methods which allow of a good aseptic technique. An animal bladder can be inserted without any undue handling on the part of the operator, and without coming into contact with the vulva or vagina.

Apart from the cases in which a macerated foetus was delivered, all the infants in this series were born alive.

The principle underlying all instrumental methods of induction of labour is essentially crude, but in the present state of our ignorance as to the cause of the onset of labour we have to rely on these crude methods in many cases. We must not, therefore, expect entirely satisfactory results from an essentially unsatisfactory operation, but until we are in possession of a more rational principle there can be no objection to attempting to improve the details of an instrumental method of induction.

In publishing these results stress has been laid on the disadvantages and dangers, equally with the advantages, and although it may seem that attention has been drawn to an imperfect method of inducing labour, there is no doubt that it has some advantages over other methods in common use. The lessening of the induction interval is a very real advantage of the animal bladder method, and at the same time the disadvantages associated with it seem to be no greater than with other instrumental methods of induction.

THE PRESENT POSITION OF X-RAY THERAPY IN MALIGNANT DISEASE.*

BY

F. HERNAMAN-JOHNSON, M.D., D.M.R.E.,

RADIOLOGIST TO THE FRENCH HOSPITAL, LONDON; PHYSICIAN IN CHARGE, X-RAY AND ACTINOTHERAPEUTIC DEPARTMENT, CROYDON GENERAL HOSPITAL.

THE present time appears opportune for a review of the position of *x*-ray treatment in malignant disease. Anyone who has followed the progress of radiotherapy during the past twenty-five years cannot have failed to note what might be termed a periodicity in the favour shown to *x* rays and radium respectively. Just before the war radium was beginning an era of popularity.

At the Annual Meeting of the British Medical Association in 1914 the Section of Radiology arranged a debate, which I had the honour of opening, on the relative value of *x* rays and radium in malignant disease. The chief points claimed in favour of *x* rays were availability, unlimited quantity, and, most important of all, evenness of distribution in the tissues, owing to its being possible to use an *x*-ray tube at a considerable distance from the patient. On the other hand, the advantages of radium were set forth as follows: It could be brought into intimate relation with malignant growths, either by its introduction into cavities such as the oesophagus, or by actually burying radium tubes, or by inserting multiple needles—the latter procedure having been advocated by Professor Joly of Dublin in May, 1914, and a little later by Dr. Stevenson, also of that city. It was, moreover, claimed that, apart from questions of quantity, distribution, etc., radium rays—by which were chiefly meant gamma rays—were qualitatively of more value than *x* rays. There was said to be a further advantage in the standardization of dosage, or rather of output, which in the case of radium depended only on the quantity of radium and thickness of filter used; whereas the *x*-ray tube of that period was difficult to control. To some extent the upholders of the *x* rays admitted the impeachment, but claimed that, with technical advances, the output of *x*-ray tubes excited at a high voltage would more nearly approach the gamma ray in quality, and that exact control of output would also be secured.

It is interesting to note that radium, although in a sense the most dynamic of the elements, must, as a therapeutic agency, be regarded as static. By this I mean that the radium in use to-day is the same agent precisely as was in use twenty years ago, although the mode of its application may differ. Not so with *x* rays. Despite the war, the prophesied developments of the *x*-ray tube did in fact occur. The introduction of the hot cathode tube by Coolidge in America made the control of output easy, and later developments gave us *x*-ray bulbs capable of standing up to a quarter of a million volts for continuous running.

Working with voltages of this order, the directors of the gynaecological clinic at Erlangen claimed a high percentage of "cures"—three to five years—in cases of carcinoma of the cervix uteri such as previously had been dealt with by panhysterectomy. Their claims as to the value of their treatment in other forms of cancer were very modest, but an idea was unfortunately promulgated in this country that the "new *x* rays" were of almost equal value in all forms of cancer. The technique as originally introduced required the administration of a so-called "lethal dose" at a single sitting. With the outputs then available this meant seven or eight hours' continued exposure. Severe anaemia and violent sickness were often produced, and many patients died from the effects of the treatment. It is to the credit of British radiologists in general that they were not carried away by this craze; in fact, a joint letter was sent to the *Times* warning the public against exaggerated hopes.

The doctrine of the "lethal dose," which was the *therapia sterilizans magna* of Ehrlich applied to cancer, was bound to be discredited, for it disregarded the part

* Abstract of an address to the Croydon Division of the British Medical Association, May 1st.

played by the local and general reaction of the patient. By the time the medical and lay public in England had become interested in it, the theory was already going out of favour in the country of its origin, and as it faded into the background the technique founded upon it was correspondingly modified. The original intensive dose was divided at first over days, and then over two or three weeks. It became, in short, no longer an "intensive dose," but a course of deep therapy.

The years 1913 and 1914 may be described as boom years for radium; 1922 and 1923 were boom years for the new *x*-ray therapy. After 1923 the latter began to decline in favour, and last year (1928) radium was once more in the ascendant. Yet the problems are still essentially those of 1914; radium is scarce; efficient *x*-ray plants are almost everywhere available. *X* rays are unlimited in quantity, and can be evenly distributed over any desired area. At present the burying of radium is greatly in favour; the chief advances in technique over that in use fifteen years ago consist in the use of more numerous foci of irradiation —radon seeds or radium needles—and a wider encirclement of the growth to be attacked.

In certain circumstances the method succeeds admirably. In early carcinoma of the tongue operative removal is already obsolete, and early uterine carcinoma will probably soon be treated by radium alone. It is in the later and more extensive cases that failure occurs.

Realizing the limitations both of surgical implantation and of surface applications, the Paris Radium Institute has been using relatively large quantities of radium at a distance of 10 cm. or more from the skin. Here we see the wheel in full circle; this is an approach to the technique of deep therapy. In fact, the massive stands used in deep therapy have been utilized to carry the heavy lead box, weighing scores of pounds, which contains the four or five grams of radium which are necessary for the purpose. The cost of the radium for such an apparatus is in the neighbourhood of £50,000, representing interest of at least £2,400 a year. Furthermore, Dr. Regaud of the Paris Radium Institute is aware that this new technique is an imitation of established *x*-ray procedure, and he warns radium enthusiasts that no final verdict can yet be given as between the natural gamma rays of radium and the artificial gamma rays generated in an *x*-ray bulb.

Let us now turn to the hard facts we have to face in this country. All *x*-ray departments in hospitals with large out-patient clinics are crowded out with cancer cases. To change from *x* rays to radium we should need in England alone more than the whole world's present supply of radium. It is quite obvious that *x* rays must be used for many decades to come, and advocates of radium who decry their use do a disservice, not only to *x*-ray workers, but also to the public. In actual fact the hospital type of patient is more often than not a more suitable subject for the exhibition of *x* rays than of radium, for it is in this class of the community that malignant disease is often neglected until it is widespread. This is not usually the doctor's fault, but is due to ignorance, carelessness, or fear on the part of the patient. The most notable examples occur in middle-aged or elderly women who allow a uterine carcinoma to spread until the whole pelvis is infected before seeking medical advice. Such a case is the following:

A married woman, aged 63, in March, 1928, gave a history of irregular loss for six months, the *menopause having* occurred ten years before. The vaginal vault was indurated, the cervix irregular, and the uterus fixed. Treatment by deep therapy produced disappearance of all pain and discharge. In June the patient was doing well and had a course of light treatment. A precautionary dose of deep therapy treatment was given in November. The condition was quite satisfactory when the patient was last heard of about a year after the first treatment.

In a considerable proportion of such cases it is possible to dry up all bleeding and discharge, and to abolish pain. The patient returns to ordinary duties for six, eight, or even twelve months, and then usually succumbs very quickly to an acute recurrence.

I say nothing about the "cure"—using the term in the same sense as the surgeons do—of early carcinoma of the cervix by deep *x* rays alone. In this country we have not had any chance of treating such cases; but I have never heard that the Erlangen claims of 70 per cent. five-year cures in this particular field have been disproved.

Then there is the extensive inoperable carcinoma of the breast—perhaps already ulcerating when the patient first comes for treatment. Here a preliminary course of *x* rays, followed by palliative surgery, is usually called for; then, after healing of the wounds, further *x*-ray courses, alternating with, or combined with, ultra-violet light treatment.

As regards the quality of *x* rays to be used, a great controversy has gone on in the past between the advocates of medium and very hard rays. The general consensus of British radiological opinion, as voiced in a British Medical Association debate at the Annual Meeting in Edinburgh (1927), was that, in breast cancer, medium rays were preferable to very hard ones. My own belief, based upon the treatment of many hundred of cases, is that both types of radiation are necessary. Invasion of the skin, in the form which looks like multiple flat warts, responds best to unfiltered or very slightly filtered rays of medium quality. For mediastinal growth, and for metastases in bone, deep therapy is necessary. It is also often the only treatment that will at times relieve the pain and temporarily stay the progress of that terrible affliction oedema of the arm. I refer to the oedema which is the result of recurrence, and not that which is caused by contraction of scar tissue after operation.

In breast cancer, post-operative irradiation is of great importance. X-ray treatment used solely as a preventive measure has been accused of doing actual harm; and this accusation has been at times justified. If radiotherapy is to avoid this reproach it is necessary to bear in mind certain principles. A large dose of *x* rays has a depressing effect upon the system as a whole. Unless the dosage has been unduly concentrated the depressing effect is only temporary; but during this period, which may be regarded as a negative phase, a latent metastasis, which might otherwise give no trouble for years, is apt to be freed from restraint. When a patient is apparently sound it is wrong to do anything to him that may depress his powers of resistance even for a short time. I need hardly, before an audience of clinicians, stress the point that the body *does* put up a resistance against the spread of cancer, and that such resistance sometimes gives way in dramatic fashion. We must, then, for safe prophylaxis, use a mode of treatment which is, in the first place, known to be effective where there is actual growth, and, secondly, which improves the patient's general health. As regards the first essential, experience has shown that by a careful gradation of doses a primary or secondary nodule in the breast may often be caused to disappear, without there being any constitutional symptoms whatever. But something more than this is desirable. We must actually make the patients feel better. If they are anaemic and below weight, they must be brought up to a healthy standard. Two years ago I had some patients suffering from actual carcinomatous lesions who had ceased to respond to *x* rays, and appeared to be going rapidly downhill. As an experiment, I put them on to treatment by mercury vapour lamp. Some of the results were remarkable, as the following case will show.

An unmarried woman, aged 67, suffering from carcinoma of the left breast with glands in both axillae, was given a course of superficial *x*-ray treatment in April, 1927. A gland in the right groin had previously been excised, but the other lesions were not removed. The patient did not respond to the treatment; she lost weight and was terribly depressed. Mercury vapour lamp treatment (general) was started, and immediate improvement was noted. By December, 1927, the patient had put on 6½ lb., and she had become cheerful. There was a further gain in weight during 1928. The nodules have been kept in check by deep *x* rays, and the patient is in good health to-day.

I have no hesitation in claiming that a combination of *x* rays and light will in some cases add months or even years to a patient's life. The effect of the light is a constitutional one, analogous to what occurs in patients suffering from lupus and other tuberculous lesions. But while tuberculous lesions may disappear under light alone, although the diseased areas are shielded from it, cancerous nodules are merely arrested for varying periods; they do not become smaller. The arrest, even though in many instances temporary only, is accompanied by a gain in weight and by a feeling of restored well-being. Many patients say: "the light treatment is life to me." Is it not, therefore, rational to apply such treatment as a

preventive measure? At the least, the patient feels better for it; and, as recurrences must have a microscopic beginning, surely a treatment which can check an established growth must in many cases enable the system to repel an invasion which has as yet gained little force.

In conclusion, I feel that I must, even at the risk of prolixity, hark back once more to the case of the patient suffering from chronic recurrent carcinoma of the breast. Have you ever asked yourselves what happened to such patients before the days of x-ray clinics? I will tell you what happened. For months, sometimes for years, they lay and festered in their homes, the victims of horrible ulceration, more loathsome than leprosy. I can myself remember entering homes where the stench of the cancer patient not only permeated the whole house, but seemed to rush into the street, overwhelming the visitor before he had even crossed the threshold. Such cases must now be rare indeed, and that they are to-day the exception is due to the care bestowed on them in the out-patient x-ray clinics of the general hospitals. The aim of these clinics is to keep the breast patient upon her feet—free from pain, cheerful in mind, and physically unobjectionable—until a final rapid internal spread of the disease removes her after but a few weeks of bedridden life. On the whole this aim is accomplished, and it can be accomplished more readily now than was the case even two or three years ago. This is a record to be proud of. There is a cry at present of "new lamps for old"; but let us remember the Arabian Nights tale, and be quite sure that the old lamps are valueless, and the supply of new ones adequate, before we throw them away.

SYCOSIS BARBAE.*

BY

JOHN T. INGRAM, M.D.Lond., M.R.C.P.Lond.,

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, THE GENERAL INFIRMARY, LEEDS; LECTURER IN DISEASES OF THE SKIN, UNIVERSITY OF LEEDS.

This paper is limited to a consideration of the subject of coccogenic sycosis or sycosis barbae, a simple staphylococcal infection of the hair follicles of the beard area in the adult male. Sabouraud[1] has referred to sycosis barbae, with reason, as "un des opprobres de la dermatologie." Textbooks unite in describing the condition as essentially a chronic process, difficult to cure; and discuss treatment, with little enthusiasm, in terms of years. It is wise that the views of the many upon such a malady should be ventilated from time to time, and it is the object of this paper to promote such a discussion.

Pathology.

An external infection of the hair follicles by the *Staphylococcus pyogenes aureus* produces inflammation which proceeds to abscess formation within the follicle, and is confined, in the main, to that portion of the follicle superficial to the neck of the sebaceous gland. The deeper portions of the follicle are rarely involved. This is the pathology of the condition, and it should be emphasized, first, that the infection is probably always of external origin, and secondly, that there appears to be no further complicating factor in the first instance, no question of a particular constitutional factor, and no question of any local or general state of susceptibility.

Diagnosis.

A correct diagnosis at the onset of any infective process affecting the beard area is of prime importance. The differential diagnosis is not a difficult one, and it is useful to bear in mind here that sycosis barbae—presenting punctate follicular abscesses with surrounding erythema—was so named on account of its resemblance to the yellow pips set in the pink pulp of the inside of a fresh fig. Impetigo, ringworm, seborrhoeic dermatitis, and seborrhoeic sycosis are the conditions most likely to present difficulty in diagnosis.

Impetigo is a vesicular dermatitis primarily, as opposed to a pustular folliculitis, and this should be sufficient differentiation. If treated with ointments, impetigo is commonly the forerunner of sycosis barbae, but this is the fault of treatment. Ointments tend to spread the eruption, to increase the period of infection, and so, by creating a chronic infective condition of the skin, favour the development of a secondary staphylococcal folliculitis. Impetigo should be treated with antiseptic lotions or powders.

Ringworm of the beard area is usually of the kerion type, and individual lesions—somewhat resembling boils—are red and boggy. The suspicion of ringworm is confirmed if infected hairs can be removed from their follicles without experiencing any resistance whatsoever. The fungus can be demonstrated microscopically.

Seborrhoeic dermatitis and *seborrhoeic sycosis*, unlike sycosis barbae, never affect the beard area alone. The moustache area is commonly affected, and the eyelids invariably present a chronic blepharitis. The scalp, the eyebrows, and other hairy parts of the body, as well as the flexures, may be involved. The importance of the diagnosis here lies in the recognition of the seborrhoeic diathesis and the special susceptibilities of the patient, which factors must be borne in mind in treatment.

Etiology.

Sycosis barbae is admittedly a disease confined, in the main, to the hospital class of patient, whether seen in private or hospital practice. Why should this be so?

Is it not likely that the solution of this first problem may have some bearing also upon the mysterious chronicity of this disease? For it is mysterious that a simple staphylococcal infection of the superficial parts of the hair follicles should resist treatment as does sycosis. Focal sepsis, sensitization, the excited or the uncleanly hand of the barber, the use of blunt razor blades, and even the colour of the hair, have all been called in to explain these mysteries, or rather the mystery of sycosis barbae as a whole; but they do not seem in any way to bear upon these two outstanding features—of class distinction and of chronicity.

Inquiry will elicit the fact that almost 100 per cent. of the sufferers from sycosis barbae are persons in the habit of shaving irregularly. He who shaves daily, and he who shaves not at all, rarely falls victim to the barbers' rash. It is this distinction in the personal toilet habits of the upper and lower classes which accounts for the incidence of the disorder being low in the one and high in the other. The factor of daily shaving is not merely of interest from the etiological standpoint, but is of the utmost importance in treatment. That hairy surfaces which are allowed to grow a stubble of hair are prone to irritation and infection is commonly observed; the boil or carbuncle on the nape of the neck is a daily instance of this.

While improper toilet, as well as improper treatment, may be a cause of chronicity in sycosis barbae, there are two other features which must not be overlooked. Septic infections discharging externally—particularly if adjacent to the beard area—may constantly reinfect the beard. Fissures at the angles of the mouth and about the nose, infections of the vestibule of the nose and of the external auditory meatus, infected teeth and gums, boils, whitlows, etc., commonly contribute to the chronic nature of a coccogenic sycosis, and must be cured before that condition will resolve.

Finally, in cases of long standing, the development of sensitization in the tissues affected may have some small bearing upon the course of the disease, but it is of little importance in treatment until the infective process has been eradicated. That the factor does enter into the constitution of these cases is shown by the following, cited from my own practice.

A man, aged 27, had previously suffered from sycosis barbae, which had at long last yielded to treatment. He presented himself, at this time, complaining of persistent irritability and redness of the beard area, which had replaced the old sycosis. The non-infective, papular, erythematous eruption seen was diagnosed as a sensitization phenomenon, and cleared after the administration of three small doses of x rays. About twelve months later the patient received a course of staphylococcal vaccine treatment for an infection in the upper respiratory tract, and the first of these injections caused a relapse of the papular erythema of the beard area which persisted throughout the course.

*A paper read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Manchester, 1929.

TREATMENT.

To be effective the treatment of sycosis barbae must be based upon a consideration of the etiological factors which have been stressed here; further, it must have due regard for the pathology of the disease, and must show a proper appreciation of the physiology and the anatomy of the part treated.

The first essential is that the patient must shave daily, no matter what the state of the beard area or the stage of the infection. For the comfort of the patient, he should use a sharp razor.

Secondly, any infective lesions other than the sycosis—fissures, infections of the vestibule of the nose, and of the external auditory meatus, etc.—must be treated, and must be cleared up before a cure of the sycosis can be expected.

Thirdly, a strongly caustic, antiseptic lotion must be applied with a view to eradicating the infection from the follicles; a weak application is not effective. The lotion should be dabbed on and allowed to dry on. Wet lint dressings, masks, etc., should not be employed.

Many prescriptions meet these requirements; one of the best is the eau d'Alibour of the St. Louis Hospital, Paris, which contains copper sulphate 4 grains, zinc sulphate 6 grains, camphor water to the ounce. At first this may be applied at night only, and a lotion or liniment of calamine may be used by day.

Finally, at no time and at no stage throughout the treatment of a case of sycosis barbae should an ointment be prescribed. There can be very little doubt but that the use of ointments in sycosis barbae—and in a number of other conditions—has been and still is responsible, in large part, for the persistently bad results of treatment. There is no reasonable basis, physiologically or anatomically, for the application of an ointment to the skin in any infective condition when that process is accompanied by the discharge of serum or pus—and especially when follicles and glands are involved. The vital functions of the whole of the skin covered, and sealed, by the ointment are seriously interfered with, more particularly the functions of respiration and secretion. The result is that the affected area passes rapidly into an unhealthy state and is readily irritated by the small proportion of antiseptic in the application. Meanwhile, the infected follicles, having their apertures blocked, now function as ideal bacteriological culture tubes, and the last state is worse than the first.

The prolonged use of fomentations, wet lint dressings, and even dry masks, similarly interfere with the normal functioning of the skin and impede the process of healing.

These simple measures usually succeed in eradicating the infection, and it is rarely necessary to invoke the aid of the more complicated forms of treatment so often practised.

The idea that *x*-ray epilation is necessary for proper drainage of the follicles is untrue, and the analogy so commonly quoted—the opening of an abscess by the surgeon—has absolutely no basis in fact, either anatomically or pathologically. It is, of course, more easy to treat a case that has been epilated, but *x*-ray epilation demands great skill and care in the operator to ensure that no damage is done to the skin. If *x*-ray epilation is resorted to in an obstinate case, it is still most important to resist the desire to apply an ointment subsequently, or the whole purpose of the epilation is undone.

The use of drugs internally, the intramuscular injection of metals, the application of so-called antivirus, and the exhibition of vaccines appear to me to add unnecessarily to the tortures of the damned. Most of these produce some measure of relief, but no measure of cure.

When the infective process in sycosis barbae has been dealt with there sometimes remains a papular erythema about the mouths of the follicles. This condition readily responds to a few small applications of *x* rays.

PROGNOSIS.

The prognosis in sycosis barbae is, in my opinion, good. Few cases should require treatment for a period of longer than three months, and cases diagnosed early will clear up in the course of a few weeks.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF CHRONIC COCCOGENIC SYCOSIS (BARBERS' RASH).

THE treatment of this chronic pyogenic folliculitis of the beard, moustache, and scalp regions has always been, I feel, the despair of the unfortunate patient suffering from the disease, and of his doctor, who is unable to do very much for him. The difficulty in the treatment of the condition lies in the fact that this folliculitis is too deep to be affected by ordinary antiseptic treatment, and yet is not deep enough to be modified by vaccines. X-ray treatment, also, is practically useless because the condition is purely a folliculitis, and the hairs in the diseased follicles are not invaded by the cocci. Epilation by means of *x* rays does not destroy the majority of the infecting organisms, as it does in those diseases due to the higher fungi, such as tinea capitis and certain types of trichophytic affections of the scalp and beard regions, where the hairs are primarily infected, and the folliculitis is only a secondary infection.

After vainly trying all kinds of treatments for nearly ten years in the skin department at the General Hospital, Birmingham, I have gradually evolved the following method of dealing with the condition. It is not a "lightning cure," and there is nothing very unusual about it, but, if it is employed properly, it will render the sufferer presentable in a very short time, and cure him eventually.

The treatment may at first sight appear to be rather *complicated, but it is not really so. It should be carried out only once a day*, and with the average patient should not take longer than ten minutes. None of the steps should be omitted, since they all have their *raison d'être*.

1. Epilate infected follicles and evacuate pustular lesions with a clean needle.

2. Wash the affected parts, using Midgley's 10 per cent. superfatted sulphur soap.

3. Dry the parts, leaving them slightly damp by mopping with a towel.

4. Apply the following iodine solution, with a tampon of cotton-wool, all over the affected parts, fairly hard:

Iodine (without potassium iodide)	4 grains
Spirit (90 per cent.)	1 oz.

5. Allow to dry.

6. Smear the following sulphur lotion, sparingly, all over the affected parts:

Sulph. precipit.	1–2 drachms
Spt. camph.	1 drachm
Lot. calaminae	ad 8 oz.

7. Allow to dry.

8. Apply very sparingly a small quantity of the following zinc cream all over the affected parts:

Zinci oxidi	15 grains
Neutral yellow vaseline	1 oz.

9. Dust over sparingly with pure talcum powder.

The patient, in my opinion, should not shave more than twice a week. When he does so he should first epilate the infected follicles; then wash with sulphur soap; then shave with a very sharp razor; then wash again with sulphur soap; and then carry on with the treatment as suggested.

The strength of the sulphur lotion used is to be varied with the degree of inflammatory reaction present in the skin, and the tolerance of the patient's skin to sulphur. The zinc cream must be used sparingly; if it is plastered on it will overheat the parts instead of acting as a corrective to the other applications.

It must be remembered that the patient's general health and occupation have an important bearing on the chronicity of the affection. Septic foci should be looked for, especially teeth, and dealt with. Working in ill-ventilated, overheated workshops is bad, since it lowers the vitality of the patient and converts his hair follicles into culture tubes for the *Staphylococcus aureus*. For the well-to-do a holiday in Switzerland, or in a dry place well above the sea level

in the British Isles, is ideal, and will often shorten considerably the time necessary to effect a cure.

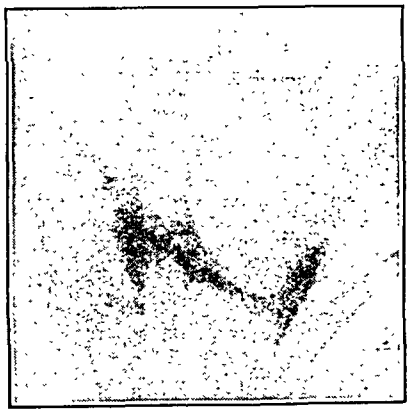
In conclusion, I wish to add that the above treatment is thoroughly impregnated with the teaching I received from Professor Sabouraud; if my colleagues find it useful, as I know they will, they must be grateful to a large extent to that excellent teacher of common-sense dermatology.

Birmingham. JAMES AVIT SCOTT, M.D.

AN UNUSUAL TYPE OF DISLOCATION OF THE SHOULDER.

LUXATIO ERECTA is a rare subvariety of subglenoid dislocation of the shoulder, in which the arm is abducted and displaced vertically upwards, the head of the humerus remaining below the glenoid cavity. The following is an instance of the condition, which appears to be sufficiently uncommon to be worthy of recording.

The patient, a man aged 27, was riding a bicycle, which skidded, throwing him to the ground. When he regained his feet his right arm, which lay by his side, felt numb; to relieve



this he raised the elbow and abducted the arm with his left hand. The right arm immediately assumed the attitude shown in the *x*-ray photograph and remained fixed in this position. The numbness was at once relieved.

When seen, shortly after the accident, the appearance of the patient sitting with the arm raised and the forearm resting on the top of the head was so striking that there was no difficulty in recognizing the condition as one of luxatio erecta. The head of the humerus could be felt lying on the lateral aspect of the chest wall below the axilla. He was given a general anaesthetic; slight traction on the arm in an upward direction combined with upward pressure on the head of the humerus easily effected reduction of the dislocation.

Subsequent *x*-ray examination revealed that there was also a fracture of the great tuberosity of the humerus but no displacement of the fragment.

Newcastle-on-Tyne.

ACUTE APPENDICITIS COMPLICATING DOUBLE OVARIAN CYST IN A YOUNG GIRL.

THE following case is unusual, and seems worthy of record.

On July 1st I was called to see a very healthy, well-developed schoolgirl, aged 14 years and 9 months, in whom menstruation had commenced at the age of 12, and had continued with absolute regularity. Twenty-four hours previously to my being consulted she was seized with acute abdominal pain, unceasing in character, and situated in the right iliac fossa. When I saw her she had a normal temperature, a pulse rate of 80, and there was tenderness and resistance in the right iliac fossa. A firm and elastic central swelling occupied the hypogastric area to within two inches of the umbilicus; it gave the impression of being a full bladder, but that organ was empty. A diagnosis of acute appendicitis and ovarian cyst was made, and the patient was removed to hospital.

Subsequently, on opening the abdomen in the mid-line, the lower part was found to be occupied by an ovarian cyst of the right ovary, the size of a coco-nut, to which was adherent a large mass consisting of omentum and several coils of small gut. These were separated and the cyst was removed; at one point it was very soft and inflamed. The pelvis was now examined, and on raising the uterus a second cyst, of the same size as the first, was found impacted and adherent in the pouch of Douglas. This was formed from the left ovary, and after considerable difficulty it was freed and removed. The mass of adherent omentum detached from the first cyst was then examined, and after some time the tip of an acutely inflamed appendix was found in its midst. This was traced to the caecum, ligatured, and removed. As careful a peritoneal toilet as possible was made, and the abdomen was closed without drainage.

The patient made an uninterrupted recovery, and was discharged from the hospital on July 27th.

A pathological examination showed no malignancy in either tubes or ovaries, but demonstrated the almost entire destruction of both ovaries by the large follicular cysts and multiple small ones.

The case is noteworthy in view of the age of the patient, the regularity of the menstrual cycle, and the history of uniform good health up to the time of the acute condition.

Harrow-on-the-Hill. C. F. MAYNE, B.Ch.

DIURETIC EFFECT OF NOVASUROL.

THE following case, treated by novasurol, is interesting in view of the copious diuresis produced.

The patient, an ex-policeman aged 58, was admitted to the General Hospital, Birmingham, on February 12th with ascites and very marked oedema of the legs, back, and scrotum; the swelling had been coming on gradually for about twelve months. He was cyanosed and very breathless, and the blood pressure was 200/140; his blood urea was 71 mg. per cent., the urine being absolutely loaded with albumin; no casts were present. Venesection gave him some relief.

For the first fifteen days the average urinary secretion was 25 oz. daily, and he was becoming much more waterlogged. On February 27th he was given 1/2 c.cm. of novasurol, and during the night he passed 34 oz. of urine (measured) and literally flooded the bed besides. The amount of novasurol he received during the next nine days, with the quantity of urine exercted, is shown in the following table.

Date.	Novasurol.	Excretion.
February 27	1/2 c.cm.	26 oz.
,, 28	1 ,, ...	34 ,,
March 1	1 ,, ...	84 ,,
,, 2 No record		
,, 3	—	40 oz.
,, 4	1 c.cm.	40 ,,
,, 5	—	100 ,,
,, 6	1 c.cm.	314 ,,
,, 7	1 ,, ...	150 ,,
,, 8	—	146 ,,

Since March 7th his daily secretion has averaged 110 oz.; he has now lost all his oedema and is quite comfortable, sleeping well and having a good appetite. His average daily intake is only about 50 oz.

I may say that before being given novasurol he was given 10 grains of ammonium chloride every four hours for three days, and its administration has been continued. Only on one occasion, and that on the day following the last dose of novasurol, did he have any diarrhoea, and then without any obvious colitis.

I am indebted to Dr. K. Douglas Wilkinson, honorary physician to the General Hospital, Birmingham, for allowing me to publish this case.

CYRIL E. PERRY, M.B., Ch.B.,
General Hospital, Birmingham.

HYDATID CYST OF THE HEART.

THE following case appears to be of sufficient medico-legal interest to justify recording.

In April, 1928, the body of a well-nourished male Iraqi, about 30 years of age, was brought to the Royal Hospital, Baghdad, for post-mortem examination. He had been found dead in bed that morning, having retired the night before in apparently normal health. A proprietary preparation of digitalis was found among his belongings. It was known that he had been in the habit of saying to people that he suffered from heart disease, but apparently he never stated what symptoms actually troubled him. In Baghdad he had not sought medical advice, and a doctor who had treated him in Mosul from twelve to six months prior to his death unfortunately could not recall any clinical details. To his employer and companions his behaviour and condition had never appeared abnormal.

At the post-mortem examination the right side of the heart was found to be engorged, the blood being markedly venous. A hard tumour the size of a goose egg (which proved to be a hydatid cyst) was felt situated in the interventricular septum; it projected equally into both ventricles, and a small orifice communicated with the left ventricle. The interior of the cyst contained an ante-mortem clot. All four valves of the heart were structurally intact. No cysts were found elsewhere in the body, and the remaining organs were healthy. The cyst wall was calcified and varied from one to three millimetres in thickness. The internal surface was smooth and of a pearly sheen.

The specimen is preserved in the Museum of the Royal Iraq College of Medicine, Baghdad.

I am indebted to the Director of Public Health, Iraq, for permission to record this case.

NORMAN L. CORKILL,
Civil Staff Surgeon, Baghdad.

Reviews.

CHILD PSYCHOLOGY.

THREE additions to the International Library of Psychology, Philosophy, and Scientific Method have recently been published, all dealing with the interesting but difficult problem of child psychology. *Judgment and Reasoning in the Child*[1] and *The Child's Conception of the World*[2] are translations into English of two volumes of a great work by Professor JEAN PIAGET of the University of Geneva, and a number of collaborators who have been working under his direction at the J. J. Rousseau Institute. The first of these books, together with one which preceded it, deal with the problem of child logic. An attempt is made to discover whether child thought, which differentiates itself from every other kind of thought, both by the interests which guide it and by its means of expression, cannot also be distinguished by its logical structure and method of functioning. Thus the problem considered is an analysis of the form and functioning of child thought, the method utilized consisting in observations of children's behaviour when confronted with those conjunctions which denote causality (because, for, therefore, etc.) and with those expressing antithetical relations (*in spite of, even* though, although, etc.). In the second volume Professor Piaget considers the problem of the content of child thought or the system of intimate beliefs as to the nature of things which the child entertains. A full account of the special method employed by the author is given. It is pointed out that this is both difficult and tedious, and that it demands also an outlook, the fruit of at least one or two years' full training. The great care taken in the investigations here described makes the conclusion reached of definite value and significance.

The third volume, *The Growth of the Mind*,[3] is a translation of a work by Professor K. KOFFKA of the University of Giessen, which is intended to serve as an introduction to child psychology. This book will be especially interesting to the student of psychology because it embodies a consistent attempt to give a new and wider application to certain principles of psychological theory and research which have recently been advanced under the name of the *Gestalt-Theorie*, and to demonstrate their significance in the interpretation of childhood. The Gestalt theory is opposed to the conventional view that the consciousness of the newborn infant is nothing but a confused mass of sensations (original chaos). It holds, on the contrary, that the first phenomena are *qualities* or *figures upon a ground*. The phenomenal appearance in consciousness divides itself into a given quality, and a ground upon which that quality appears—a level from which it emerges. Such a coexistence of phenomena in which each member "carries every other," and in which each member possesses its peculiarity only by virtue of, and in connexion with, all the others, is called by Koffka a *configuration* (Gestalt). This Gestalt theory is probably very important. Observations are cited which suggest that specific emotional qualities are more primitive and more elementary contents of perception than those we learn of as "elements" in the textbooks of psychology. A certain order or "meaning" dominates experience from the beginning. Thus at quite an early age the child's reactions to a "friendly" face and to an "angry" face are different, and this difference obliges us to conclude that "friendly" and "angry" faces are phenomenal facts to the infant, and not mere distributions of light and shade. That such subtle "intuitive" differentiations should be "given" in the child at the outset rather than acquired by association, according to the usual view, certainly does not diminish the mystery of life. Rather would it appear to enhance it. This interesting book includes a useful discussion of the behaviourist psychology, and in the development of his thesis the author draws freely upon Koehler's unique researches on the mentality of chimpanzees. We have here a new orientation of psychology, and every serious student of this subject would be well advised to make himself acquainted with this volume.

These volumes exemplify an increasing tendency to devote research to the problem of the psychology of children. A like tendency is manifested in the sphere of abnormal psychology, and a vast amount of literature is now being published dealing with the maladjustments of children. It would therefore appear suitable to include in this notice a volume by Miss MARY CHADWICK, a member of the College of Nursing, on *Difficulties in Child Development*.[4] The writer is an orthodox Freudian, and thus the problem is approached from the standpoint of a specific theory of psychic development. For this reason many of the generalizations in this work will probably be found unconvincing to some of its readers, such, for instance, as those relating to character traits and infantile eroticism —the spendthrift and verbally incontinent individual is one who suffered from relaxed sphincters in childhood, etc. Miss Chadwick's aim is to put forward in a simple and direct manner views and discoveries made by Freud and his followers, now scattered in many books written upon the development and upbringing of children, and to condense these into a more convenient form for parents, teachers, and nurses, and others who are interested in the problems of child life. The book includes an extensive bibliography, and it is evident that the writer has expended considerable labour in its production. It contains a good deal of useful advice and is eminently readable. However much some of the theoretical principles elaborated in this work may fail to carry conviction, the writer's insistence upon the need for giving at least as close attention to the psychological difficulties of children as to their physical health will meet with general assent.

RADIUM IN SURGERY.

IN *Radium and its Surgical Applications*[5] Mr. H. S. SOUTTAR has provided within small compass an interesting and easily read summary of the present position of radium therapy. Knowledge is accumulating rapidly, and methods are changing month by month, so that the time is scarcely ripe for large textbooks on the subject. A book of only 60 pages can be entirely rewritten at frequent intervals, and so its message can be kept fresh. The first chapter is formed by an account of the physics of radium which has been already printed in the *British Medical Journal*. The other ten chapters describe the apparatus required, the sensitivity of the tissues to radium, and the treatment of malignant disease in the different regions of the body.

In a work of such brevity the author is naturally unable to develop his arguments at length, and it is almost inevitable that he should take up a rather more dogmatic attitude than the subject warrants. His statement, for instance, on page 14, that a thickness of 0.5 mm. of platinum "will absorb all but the most trivial fraction of the beta rays," will not meet with general acceptance. The fraction of beta rays remaining unabsorbed may be small, but it is not for that reason trivial, and opinion is moving in the direction of increasing the screenage. There are other statements in chapter ii which might perhaps mislead the uninitiated reader. In discussing the sensitivity of the tissues to radium in chapter iii Mr. Souttar makes a considerable point of the part played by "fibrosis" and "dense sclerosis" in the stroma in destroying the malignant cells. He is here dealing with a highly controversial subject, and there are those who doubt whether correct dosage produces any sclerosis at all, so that its pathological significance, when it occurs, may be overemphasized. Further, some workers with radium have failed to find that cancer cells "become resistant to repeated doses" (p. 24), and therefore much more investigation is needed before this can be safely stated as a fact. The remaining chapters (iv to xi) are thoroughly practical, but so brief that no one must suppose himself

qualified to practise radium therapy after he has read them, though he will obtain from them an excellent survey of its possibilities, and may be stimulated to study further the new weapon that is being put into the surgeon's hand.

It is to be hoped that Mr. Souttar will soon be enabled to issue a second edition of his little volume, revised in the light of further experience. The author's line drawings are excellent, and would add considerably to the value of the book if they were more numerous.

PATHOLOGY OF SURGICAL INFLAMMATION.

MOST writers on surgical pathology are content to accept Burdon-Sanderson's definition of inflammation; some consider it impossible to arrive at any definition that is entirely satisfactory; others adopt a conventional rather than a logical definition. The latter course has been adopted by Dr. D. B. RONCALI in his very original treatise on surgical infections or inflammations.[6] He regards inflammation as a conflict for existence between a living parasite, vegetable or animal, and the host, terminating in the discomfiture of one or other of the combatants. He makes it a postulate that a living pathogenic virus, constituting the attacking party, shall be present within the tissues of the host attacked; thus the bite of a rabid dog carrying an infective agent would lead to inflammation, whereas the reaction to a non-infective bite would be excluded by the definition. This conception of inflammation is not entirely new, but authors have not hitherto made any considerable use of it in their descriptions; they generally branch off into a merely abstract description of the processes involved. Roncali, on the contrary, has strictly adhered to the point of view throughout his treatise. First, he describes the numerous parasites which the body may have to combat, enumerates the diverse means of offence which they possess, and explains the nature of the damage which they are capable of inflicting on the tissues of the host. Then an account is given of the various means of defence possessed by the host, how these are brought into play, the conditions under which they are effective or the reverse, and the various artificial methods of increasing the defensive powers by means of vaccines and serums. Finally, the actual conflict between parasite and host is followed in detail, first at the portal of entry of the parasite, secondly in the lymphatic tissues and viscera as the second line of defence, and, finally, in the blood. This method of expounding the subject is interesting in itself, and it has the further advantage of bringing the facts of pathological anatomy, bacteriology, immunology, and related matters within one focus, instead of regarding them as distinct and separate subjects of study. The present volume treats of inflammation generally, and will be followed by two other volumes dealing with acute and chronic inflammation respectively.

Adopting the view that malignant tumours are of microbial origin, Roncali necessarily includes them under the heading of inflammation, which, according to his definition, as above stated, is a conflict between parasite and host. He states, however, that malignant disease is an inflammation *sui generis*—of a particular kind. This concentration on the idea of conflict, regardless of the nature of the process involved, is of doubtful advantage; if pushed to the extreme it would lead to our regarding every reaction of the body to abnormal conditions of the environment as a conflict, and all diseases as inflammations.

ELECTRO-CARDIOGRAPHY.

IN the anomalies of the ventricular complex[7] Dr. J. ROBERT LÉVY attempts to form a basis for prognosis of cardiac disease from the electro-cardiographic standpoint. He has studied 900 cases of all ages, both clinically and electrocardiographically, and his observations on these cases are presented from two points of view. In the first place he gives a statistical study of the chief anomalies from their prognostic aspect, and, secondly, he considers the anomalies in relation to their occurrence in the different clinical types. The author concludes that the presence of anomalous complexes is a bad prognostic sign, but the prognosis is not equally grave for all forms. His conclusions, however, are of very doubtful value, for the evidence as it is presented is insufficient to warrant them. The author seems to have overlooked the necessity for adequate controls when assessing the prognostic value of any sign. For example, the prognostic value of a QRS complex of low voltage is assessed from the observation that of twelve patients who were followed, eight died of their cardiac condition within ten weeks, a mortality of 66.66 per cent. No details are given as to the age or clinical condition of the twelve patients, nor are we told the mortality of a series of cases similar in age and cardiac condition but without low voltage QRS. The same criticism applies to the evidence throughout the book.

Clinical Electrocardiograms[8] by Dr. FREDERICK WILLIUS of the Mayo Clinic is a work of reference rather than a textbook. It contains nearly a thousand illustrations of electro-cardiograms exemplifying the disorders of the heart beat and, as the author states in his preface, the text of the book is devoted entirely to the subject of reading the records themselves and their clinical significance. A bibliography is appended to each chapter, and there is a good index. The illustrations are clear and their interpretations adequate; taken in conjunction with a standard textbook the volume might be of use to those who are learning the subject.

ATLAS OF HUMAN HISTOLOGY.

STUDENTS of histology should be grateful to Professor J. SOBOTTA for the admirable and up-to-date fourth edition of his well-known textbook and atlas of histology and microscopical anatomy[9] *Lehrbuch der Histologie und mikroskopischen Anatomie des Menschen*. It is always desirable that these compilations of systematic knowledge should be reconsidered and adjusted from time to time to meet our present-day outlook and requirements. It is now eighteen years since the publication of the second edition of this book, and the author has been well advised to present this revised and greatly extended account of the subject; the third edition was only an emergency post-war reissue of the second edition, and was soon out of print.

The more attractive and valuable part of this work is contained in volume ii, which is a fairly complete atlas of human histology—a collection of beautiful plates, 24 being in black-and-white and 68 in colour, reproduced by lithographic process from the original drawings of W. Freytag, which express by a judicious blending of diagram and realism a useful and practical conception of the microscopical anatomy of the tissues. These illustrations are succinctly and fully described, together with the methods employed in fixing and staining the specimens from which the drawings have been made, in explanatory notes, with key to directional letters, on the pages facing the plates. Volume i comprises a systematic account of human histology, in which the author has endeavoured to reproduce in words the pictures of volume ii, and with the help of marginal references he hopes to facilitate the study together of text and atlas. It is a pity that the text is so overburdened with parentheses, which are often unnecessary and always hinder and confuse the reader. The arrangement of the subject is excellent, progressing from the structure of the primitive cell to that of special cells, and so to the structure of organs. Many of the descriptions are accompanied by ingenious schematic diagrams which will undoubtedly assist the student to visualize the structure of the organs described—for example, liver, spleen, secretory glands, cylindrical epithelium, etc. Special care has been given to the varieties of connective tissue and

[6] *Trattato Generale e Speciale delle Infezioni o Inflammazioni Chirurgiche.* Per Demetrio B. Roncali. Volume Primo. Stabilim. Tipografico I.N.A.G. 1929. (Imp. 8vo, pp. xiv + 336; 8 figures, 6 plates. L.65.)

Lehmanns Medizinische Atlanten, Band 9, Teil i und ii. München: J. F. Lehmann. 1929. (8 × 10, Teil i, pp. xiii + 354, 42 figures; Teil ii, pp. 384, 535 figures, 92 plates. M.48 the two volumes.)

muscle, but the histology of the blood and bone marrow has received only slight attention. The statement that megakaryocytes occur in bone marrow, "einzig und allein beim Menschen," is, of course, not correct; these cells occur in the bone marrow of all mammalia.

Excessive weight, probably inseparable from the demands of the colour printer, is a great disadvantage to these volumes; together they weigh six and a half pounds. The appendix on the use and object of the microscope seems to be out of place in a book of this character. The outstanding feature of the publication is its very moderate price; at 48 marks (bound) this is truly wonderful value for money.

A SURGEON ON INDIGESTION.

Mr. H. J. Paterson's monograph on *Indigestion*,[10] based as it is on his long experience of abdominal surgery, should be of much value to the practitioner. Mr. Paterson does not allow his surgical tastes to run away with his judgement, and in many cases is insistent that medical measures should be given a thorough trial before surgery is resorted to. Thus, in gastric and duodenal ulcer he advocates a prolonged regime of rest and careful dieting, although he is very sceptical about the results of the intensive alkaline treatment. His scorn of the advocate of this treatment who, after a "cure," suggests that, if there be any return of the symptoms, the use of the powder should be resumed for "a few days," is justifiable, but the enthusiast is always liable to expose these irrational loopholes in his armour. If rest and dieting fail, Mr. Paterson urges gastro-jejunostomy, combined with removal of the appendix, as the correct treatment. He has little use for the more severe operations of partial gastrectomy and duodenectomy in these cases, just as in intestinal stasis and gastroptosis he condemns all "pexies" as unsound and unscientific procedure. Mr. Paterson pleads very strongly for the examination of the gastric contents in all doubtful cases of digestive trouble, and thinks that if the use of the stomach tube were part of the routine of gastric diagnosis radical treatment for carcinoma of that organ would be possible in 60 per cent. of all cases. In an appendix he gives a list of apparatus for gastric analysis, suitable for use by the general practitioner, and costing less than twenty shillings. At the beginning of the book an attempt is made to classify indigestion into three main clinical varieties, under which are grouped the various diseases which may give rise to, or be associated with, these disturbances of function.

NOTES ON BOOKS.

For the medical practitioner in the tropics who has to deal with native sick in large numbers, when time, expense, and lack of assistance impose limitations, and circumstances have not permitted of his formulating his own standard treatments, the small volume entitled *The Use of Standard Treatments in the Campaign against Disease in the Tropics*,[11] by Dr. J. Neil Leitch, will be of great value. The number of diseases dealt with is small—malaria, kala-azar, cholera, hookworm infection, and amœbiasis—but the treatments advised have been standardized as the result of large experience, and therein lies their value. The method of formulating a standard treatment is explained, and can be adapted to other diseases in which certain factors obtain—namely, a specific easily recognizable cause and a known specific remedy which, administered in certain doses over a given time, will effect cure.

We were able to give a favourable account of the first edition of Labat's *Regional Anesthesia*[12] on its appearance some six years ago, and the second edition, which has now been issued, has been improved in several minor details, and rewritten as regards the chapter on subarachnoid block (spinal anæsthesia). A useful table, called "Code for regional anæsthesia of the body," from the pen of Dr. Morris Segal, has been added, and will serve to call to mind quickly the various details of position, landmarks, strength of solution, depth of insertion of needle, etc., which are required for any given operation. The illustrations, printing, and general get-up of the book are admirable, and it is a monograph that can be recommended to anyone interested in the subject of regional anæsthesia.

Jeanneney's *Cancer*,[13] translated from the French by Dr. John Gibson and Dr. John H. Watson, is a practical summary of the subject for the use of the general practitioner. Its aim is to further the campaign against cancer by helping the practitioner in making early diagnoses; within the compass of 180 small pages it describes the precancerous conditions and early signs of cancer in every part of the body. Dr. Watson has added a chapter on the organization of the campaign in Great Britain.

The Hospital for Sick Children, Toronto, has now followed the practice, which is becoming increasingly common, of publishing a volume[14] of selected articles written by members of the staff both of the hospital and of the department of paediatrics at the University. Dr. Alan Brown explains in a preface that the volume is dedicated to Miss Angelica M. Courtney, who has been director of the research laboratories of the department for the past ten years. Miss Courtney's work on the metabolism of infancy and childhood is well known, and throughout this volume there is evidence of her influence. For twenty years she has been studying her subject, and the first eight articles in this volume report various aspects of her work, either alone or in collaboration. Most of the articles have appeared elsewhere in various periodicals, but it is a fitting tribute to the work of Miss Courtney and her associates to have them conveniently collected in a well-produced volume.

The sixth edition of Professor H. Kleinschmidt's well-known little book, therapeutic vade-mecum for paediatrists,[15] has just appeared, and it shows evidence of thorough revision in the light of new knowledge. The sections on diabetes, rickets, and some of the skin disorders have been rewritten, and the doses of drugs carefully revised. Nirvanol is included for the treatment of chorea—an indication of the modern character of the book.

The proceedings of the second international conference on light and heat in medicine and surgery, which was held in London at the end of last year, and mentioned in the *Journal* on November 10th, 1928 (p. 853), have now been published as a book, which is entitled *Light and Heat in Therapy*,[16] a chapter on foam treatment being added.

The third series of memoirs presented to the Institute of Egypt comprises a bibliography of works relating to mummification, with excerpts, epitomes, critical and biographical notes, by Mr. Warren R. Dawson.[17] In his preface the author remarks on the scarcity of works of real value on a subject of such importance as the technique of mummification in ancient Egypt. Of the countless mummies discovered during the last two hundred years, few have been scientifically examined; they have been treated generally as mere curios, more space being usually devoted to a description of their cases and decorations and to speculations on the meaning of the inscriptions than to the bodies themselves. Mr. Warren Dawson's object in publishing this bibliography is to place before students the principal literary materials for studying mummification of human bodies. The frontispiece is reproduced from a portrait of Thomas Joseph Pettigrew, surgeon and antiquary, whose *History of Egyptian Mummies*, published in 1834, was the first scientific monograph exclusively devoted to the subject of mummification.

Income Tax Up to Date[18] is a pamphlet which sets out in readily available form the salient points which it is desirable to bear in mind, and illustrates them by clear examples. Naturally the compiler has found it impossible to include any detailed information on the most difficult part of the taxpayer's task, that of computing the amount to be returned for assessment, but within the limits imposed by the brevity of the publication it should be of real assistance to taxpayers.

THE LEAGUE OF NATIONS ASSEMBLY.

PROGRESS OF THE HEALTH ORGANIZATION.

THE health work of the League of Nations, which a few years ago was regarded with distrust as carrying the League into fields not within the Covenant, has received nothing but praise during the present Assembly at Geneva, and the usual talk of "stabilizing" the health budget—another term for limiting fresh activities—has not been heard.

The Campaign against Syphilis.

The report on the Health Organization was introduced by Mr. Fierlinger of Czechoslovakia. He spoke in particular of the study of salvarsan and its derivatives, which has been proceeding for some time. The Health Organization had done much, he said, to bring into use effective non-toxic remedies against syphilis. It had been hoped that the remedies now available would produce a decrease of incidence, but some doubt was expressed whether the decrease was real, and whether the treatment had the value claimed for it. Inquiries had accordingly been set on foot in university centres and dispensaries in Germany, Denmark, the United States, France, and Great Britain, and the results of an analysis of about 50,000 cases would be known towards the end of the year.

Infant Mortality.

Mr. Fierlinger also stated that an inquiry into infant mortality had been entrusted to experts from seven European countries. These experts had studied the medical and social causes of more than 7,000 deaths among children under 12 months of age, as well as of 2,000 stillbirths. One fact which the inquiry had brought out was that of every hundred deaths of children under 1 year, from eighteen to thirty-four (according to the locality) occurred during the first eight days of life. Similar investigations had also been made in four countries of Latin America, and a general report on the whole subject would be submitted next year. The country in which the inquiry aroused the keenest interest was Denmark, where national investigations were also proceeding.

Malaria.

Inquiries had been conducted by the Malaria Commission of the League in malarial districts of Europe, North America, and Asia Minor. A few weeks ago some members of the Commission landed at Bombay, at the invitation of the Indian Government, to study, in conjunction with the health authorities of the various provinces of India, the results of the measures there adopted. The delegation consists of experts in the subject from Germany, America, Spain, France, and Holland, and its aim will be to establish co-operation with the Indian health services and medical associations with a view to furthering the efforts of the Malaria Commission.

Assistance for Health Administrations.

Another matter referred to with gratification by the rapporteur was the fact that the Greek Government had recently sought the Health Committee's assistance in the reorganization of its health services. Greece was seeking to establish a modern public health service, with a trained personnel. Legislative authority had been obtained for the necessary measures. A new health organization of prefectures was to be set up in certain selected districts, and by 1934 or 1935 was expected to cover the entire country. A school of hygiene was to be instituted in Athens, the function of which would be to train all classes of health personnel, to conduct and administer the work in the different districts, and to advise the Government on public health questions. The President of the Bolivian Republic has made a similar request for assistance, and an expert was to be sent from the Health Organization to co-operate with the Bolivian health administration in the reorganization of the services. The expert chosen would act as administrative officer for two years. The "cry from Macedonia" had been heard also from China, where the National Government had invited the medical director of the League (Dr. Rajchman) to become a member of an international committee of technical advisers, and the invitation had been accepted.

Radiotherapy.

The debate on the health administration was noteworthy for a very interesting contribution from Dr. Roberta Jull, one of the members of the Australian delegation to the Assembly. She spoke of medical advances in the Pacific, and in particular of the help which both the federal and local Governments in Australia were giving in the way of subsidies to work on radiation in the treatment of cancer. A committee of the Cancer Commission of the League is also charged with the study of radiotherapeutic measures; cancer of the cervix uteri has been selected for investigation, and three experts—one from the Curie Foundation at Paris, another from the Universitäts-Frauenklinik at Munich, and the third from the Radiumhemmet at Stockholm—have been selected to help in collecting and analysing information on the results of radiological treatment at clinics and institutions in different countries where experience has extended over a sufficiently long period. Records of cases are being collected according to a uniform method in order to facilitate comparison. The question of the dangers arising from x rays is also under review. The medical director has asked public health administrations for information as to any regulations on this subject or any action taken to avoid these dangers. The health authorities of nine countries have replied that no special laws or regulations are in existence. Special committees to study the subject have been set up in Austria, Denmark, Germany, Norway, and Greece. The Industrial Hygiene Division of the Department of Public Health of Australia is also conducting an inquiry. Information received from England is to the effect that, although there are no statutory regulations on the matter, most hospitals and responsible institutions accept in their practice the requirements recommended by the X-Ray and Radium Protection Committee.

Interchanges of Health Personnel.

Several of the speakers mentioned from personal experience in their respective countries the value of the interchanges of health personnel arranged by the Health Organization. An interchange in India which took place during the early part of the present year was attended by sixteen public health officers from the administrations of twelve countries in the Far East, and a number of opportunities were afforded for studying the campaign against malaria (probably the most serious health problem in India), and against other tropical diseases, such as cholera, kala-azar, leprosy, and ankylostomiasis. Another interchange took place in Europe for the study of rural hygiene; there were twenty participants from eighteen countries, and visits were paid to rural areas in the kingdom of the Serbs, Croats, and Slovenes, Hungary, Germany, the Netherlands, and Belgium. During the final conference, held at Geneva, each participant gave an account of the work which he hoped to inaugurate in his own service as a result of the tour. Another interchange has taken place in Italy, attended by twenty-one public health officials from sixteen countries. The visit was arranged so as to give the participants a clear picture of the varying social and economic conditions in that country, as well as a good general idea of public health problems.

Control and Limitation of Narcotic Drugs.

Long discussions—one of them extending beyond midnight—have taken place in the Fifth Committee of the Assembly, which deals with social questions on the unsatisfactory position with regard to the illicit traffic in drugs. Particular attention was drawn to a memorandum submitted by the Netherlands Government on the transactions of a Dutch firm—the most detailed document which has ever come before the Opium Committee—regarding the ways in which drugs are supplied to the international illicit traffic. It shows that, although this firm's transactions did not infringe the laws in force in the Netherlands, the narcoti[illegible] firm were intended for other than [illegible] The committee believed that this Dutch traffic—which has now been suppressed—probably dealt with about half the total world production of heroin.[1]

A long discussion took place during the Assembly on a scheme for limiting the manufacture of drugs. The outstanding features of this scheme are that each Government shall notify in advance for a determined period its requirements of each of the substances derived from opium and the coca leaf that are now, or may be in the future, covered by either The Hague Convention or the Geneva Convention, and that each Government shall state from which country it will purchase its requirements in narcotic drugs for medical and scientific purposes. The Japanese delegate said that his Government was preparing a number of important reforms in the existing regulations, and it was hoped that new measures would be brought into force by the end of the year. The chief object of these measures was to check the leakage of cocaine and other drugs. The manufacture of narcotic drugs in Japan, he said, had already been reduced, and it had been decided recently that further reduction would be made within a few years' time up to two-thirds of the quantity of cocaine at present manufactured. The representatives of other Governments gave particulars of the measures taken to curb illicit traffic. The French Government has prepared a scheme under which manufacturers will be able only to handle raw materials

[1] *British Medical Journal*, February 2nd, p. 213.

up to a quantity fixed by a ministerial ordinance. Only persons in possession of a Government licence will be able to import or export, manufacture or trade in France in the drugs in question. No person who has been convicted of illicit traffic in any country will be granted a permit. A system of notification of deliveries has been instituted for exports to countries which do not employ the import certification system. It was stated that there were nine countries which must be described as drug-manufacturing countries.

The Fifth Committee passed a resolution stating that it regarded the principle of the limitation of the manufacture of morphine, heroin, and cocaine and other drugs mentioned in Article 10 of the Geneva Convention as now accepted, and requested the Opium Advisory Committee of the League to prepare plans for such limitation, regard being paid to world requirements for medical and scientific purposes.

At the close of the discussion M. Fotitch, the rapporteur on the subject, expressed his pleasure at the unanimity with which the principle of limitation by international means had been accepted; it would give, he said, an entirely fresh character to the activity of the League in this field. M. Gallavresi of Italy, the vice-chairman of the Permanent Central Board, said that his Board was now ready to supply the necessary basis for the scientific determination of the world's need for drugs.

At the instance of the British delegate, Professor Noel Baker, a further resolution was passed, recommending every State Member of the League to make arrangements for all suspected postal matter, in either the country of consignment or the country of destination, to be opened by, or in the presence of, the authorities.

The outstanding result of the discussions is the request to the League Council to take immediate steps to draw the attention of Governments to the necessity of putting into operation an effective system of administrative control of manufacture and distribution.

Vaccinations against Diphtheria and Scarlet Fever.

Preliminary inquiries undertaken in various European countries, in accordance with a decision of the Health Committee showed that a consultation between experts, and an exchange of experimental material, on the various methods of positive vaccination against scarlet fever and diphtheria and their results would be of great value. The following experts were consequently convened to a consultation in Paris on July 4th to 6th, 1929, of which a report has just been issued: Professor Th. Madsen, Copenhagen (chairman); Dr. Bie, Copenhagen; Dr. Borcic, Zagreb; Professor Cantacuzene, Bucarest; Professor Dr. R. Debré, Paris; Professor Friedemann, Berlin; Professor E. Gorter, Leyden; Dr. E. H. R. Harries, Birmingham; Dr. Hirszfeld, Warsaw; Dr. R. A. O'Brien, Beckenham, Kent; Dr. Ramon, Garches, Seine-et-Oise; Dr. O. Schubert, Prague; Dr. Temesik, Budapest. It was decided, without going into theoretical discussions of the problems under consideration, to draw up a programme of comparative experiments, to be undertaken under similar conditions in specially chosen districts with identical research material, methods, and procedure, in order to draw from the results obtained comparative conclusions for practical application.

Diphtheria.—Comparative experiments are to be undertaken: (*a*) on the Schick reaction; (*b*) on the positive immunity conferred. For the Schick reaction a homogeneous toxin is to be used, and the method is to be applied according to a detailed uniform technique. The vaccination is to be carried out comparatively with (1) anatoxin, (2) toxoid, (3) toxin-antitoxin. The following questions will be particularly investigated: (*a*) Comparison with Ramon anatoxin of the various antigens used for active immunization against diphtheria. (*b*) A comparative study of the results, varying the intervals between the injections. (*c*) The comparative effects of subcutaneous and intramuscular vaccinations, to be determined by comparing the reaction and degree of immunity conferred by the two methods. (*d*) Influence of the age of the vaccinated persons. (*e*) Influence of the environment of the vaccinated persons. With a view to co-ordination of the experiments, directions have been laid down for the preparation of a general technique applicable to all the experiments, and a standard record card has been adopted. It is expected that the experiments will cover some 20,000 cases in Czechoslovakia, Denmark, England, France, Germany, Holland, Hungary, Jugoslavia, Poland, and Rumania.

Scarlet Fever.—Comparative experiments, similar to those relating to diphtheria, are to be carried out on (*a*) the Dick reaction; (*b*) the degree of positive immunity conferred. For the Dick reaction the same toxin is to be used in each country. The reaction is to be carried out in accordance with uniform directions drawn up by the experts. In certain countries toxin prepared from local streptococcic strains will be used to provide further comparative tests. For experiments in active immunization the Danish Government Serum Institute will provide each of the countries in question with two Dick strains and one Dochez strain. From these, anatoxin is to be prepared in accordance with a uniform process laid down by Ramon, and the anatoxin so prepared will be compared with anatoxin prepared from local streptococcic strains. A uniform scheme will be drawn up for the establishment of the general technique, and records will be kept on standard forms. The experiments are to be carried out in Czechoslovakia, France, Germany, Holland, Hungary, Japan, Jugoslavia, Poland, and Rumania, and will include about 10,000 cases.

Both in the diphtheria and in the scarlet fever tests the result of vaccination is, where possible, to be assessed not only by the reaction of the skin, but also by determination of the antibody content of the serum of the person vaccinated. The results of the tests, which will thus be comparable, will form a reliable basis for a more extensive study of certain problems which it has not yet been possible to cope with owing to their extremely complicated character. A solution of the problems under discussion is, however, urgently required in order to combat some of the most frequent causes of death among children.

THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

The first meeting of the Council of the British College of Obstetricians and Gynaecologists was held in London on September 25th. The president, Professor W. Blair Bell, was in the chair. It was reported by Mr. Oswald Hempson (solicitor to the College) that incorporation had been granted and completed on September 13th, 1929.

Election of Council.

The following were elected members of the first full Council:

London:
Dame Louise McIlroy, M.D., D.Sc.
T. Watts Eden, M.D., F.R.C.P.
J. S. Fairbairn, M.B., F.R.C.P., F.R.C.S.
L. C. Rivett, M.Chir., F.R.C.S.

Provinces:
Professor A. Donald, M.D., LL.D. (Manchester).
Professor Sir Ewen Maclean, M.D., F.R.C.P. (Cardiff).
Professor Carlton Oldfield, M.D., F.R.C.P., F.R.C.S. (Leeds).
Professor Miles Phillips, M.B., B.S., F.R.C.S. (Sheffield).
Professor Beckwith Whitehouse, M.B., M.S., F.R.C.S. (Birmingham).
E. Farquhar Murray, M.D., F.R.C.S. (Newcastle).
Leyland Robinson, M.D., F.R.C.S. (Liverpool).

Scotland:
Professor R. W. Johnstone, M.D., M.R.C.P., F.R.C.S.Ed. (Edinburgh).
Professor Munro Kerr, M.D., F.R.F.P.S. (Glasgow).
T. Haultain, M.B., B.Ch., F.R.C.S.Ed. (Edinburgh).
R. A. Lennie, M.B., Ch.B., F.R.F.P.S. (Glasgow).

Ireland:
Professor C. G. Lowry, M.D., F.R.C.S.I. (Belfast).
Bethel Solomons, M.D., F.R.C.P.I. (Dublin).
T. M. Healy, M.B., B.Ch., M.R.C.P.I. (Dublin).

The following were co-opted (under Article 40) for the purpose of organization:

Professor R. J. Johnstone, M.B., B.Ch., F.R.C.S. (Belfast).
Eardley L. Holland, M.D., F.R.C.P., F.R.C.S. (London).

Election of Officers and Committee.

The following officers were elected:

President: Professor W. Blair Bell, M.D., F.R.C.S. (Liverpool).
Vice-President: Professor J. M. Munro Kerr, M.D., C.M., F.R.F.P.S. (Glasgow).
Treasurer: Comyns Berkeley, M.D., M.Chir., F.R.C.P., F.R.C.S. (London).
Secretaries:
Professor Fletcher Shaw, M.D., Ch.B. (Manchester).
H. Russell Andrews, M.D., F.R.C.P. (London).

Sir Francis Champneys, Bt., M.D., F.R.C.P., was appointed vice-patron of the College in recognition of his services to obstetrics and gynaecology, and to the College during the process of formation.

The following were elected members of the executive committee:

Professor Blair Bell	Professor Lowry
Mr. Comyns Berkeley	Mr. Rivett
Professor Munro Kerr	Professor Fletcher Shaw.

Nova et Vetera.

SURGEONS WHO WERE NEVER SURGEONS.*

BY

SIR D'ARCY POWER, K.B.E., F.R.C.S.

SURGEONS who were *never* surgeons, I may premise, are *not* to be confused with surgeons who are *no* surgeons. Of the latter there is no lack, and each will call to mind an outstanding example. By "surgeons who were never surgeons" I mean those who obtained the Fellowship of the Royal College of Surgeons of England without having practised, and sometimes without having intended to practise, as surgeons. They are much fewer than surgeons who were no surgeons, and I am at a loss to explain why some of them should have exposed themselves to the perils of a severe examination without any adequate cause. It may have been that they had acquired a liking to have their knowledge tested—a curious form of pleasure and a morbid one, as it seems to me, akin to that of those unfortunate women who develop a craze for abdominal operations to cure their "adhesions." It may be mere vanity, to show that they could acquire knowledge which they knew would be useless to them in after-life. It was often because they had achieved success in paths widely different from surgery.

There are many surgeons who were never surgeons, and I propose to give you a very short account of some of them, from knowledge obtained whilst editing Plarr's *Lives of the Fellows of the Royal College of Surgeons of England*, in conjunction with Mr. W. G. Spencer and Professor G. E. Gask, which is shortly to be published.

Richard Robert Madden.

First upon the list is Richard Robert Madden (1798–1886). He took the Membership of the College in 1829, and was elected to the Fellowship in 1855. He was admitted to the intimate circle of Lady Blessington in 1823, and became a friend of Lord Byron and Count D'Orsay. He afterwards published *The Literary Life and Correspondence of the Countess of Blessington*. He travelled much in the Levant; was one of the special magistrates appointed to administer the statute abolishing slavery in 1833 in Jamaica; became superintendent of liberated slaves; and was judge arbiter in the mixed court of commission at Havana. He accompanied Sir Moses Montefiore on a philanthropic mission to Egypt in 1840, and was employed on the West Coast of Africa to inquire into the administration of the British settlements. He lived in Lisbon from 1843 to 1846, acting as special correspondent to the *Morning Chronicle*, and afterwards went to Western Australia as Colonial Secretary. He ended his life as secretary to the Local Fund Board in Dublin, where he died and was buried as a devout Roman Catholic.

William Guybon Atherstone.

William Guybon Atherstone had an even more varied career. He was born at Nottingham in 1814, took his M.R.C.S. in 1838, and the M.D.Heidelberg in 1839. He was elected F.R.C.S. in 1863. His father, who had been a house-surgeon at Guy's, emigrated with his family to South Africa in 1819, and settled at Grahamstown. The son, after a short apprenticeship to his father, acted as staff medical officer under Sir Benjamin D'Urban during the second Kafir war, and afterwards received his certificate as a qualified medical man. Throughout his life he was far in advance of colonial opinion, and was a man of the type of Cecil Rhodes, for whom he, in some measure, made the paths straight, although the two men never met. He was keenly in favour of a Cape to Cairo railway; he wished to see a telegraph wire carried overland to Egypt, and he fostered the infancy of ostrich farming. As a prospector with a sound knowledge of geology he made many important journeys throughout the length and breadth of the land. In 1867 he identified the first diamond found at what is now Kimberley, examined it with a polariscope, and tried its hardness on glass—the window on which he experimented has since been preserved and framed. His pioneer work was recognized in 1888 by the Kimberley companies, who presented him with a valuable diamond. Atherstone was a good field botanist, an artist, and a competent musician, but as a surgeon he was negligible. In later life he was elected a member of the Legislative Assembly, and in 1884 he entered the Legislative Council.

Robert James Stone.

Robert James Stone was born in 1817, and became a Member of the College of Surgeons in 1840. In 1845 he published *The Planetary and Stellar Universe*, which was followed by a long series of textbooks on astronomy, chemistry, physiology, and health. He left England for Natal in 1857 as Superintendent of Education, and became interested in the meteorology of the colony. In 1866 he returned to London as emigration officer for Natal, and became president of the Meteorological Society. From 1874 to 1886 he was secretary of the "African" and the "Foreign and Colonial" sections of the Royal Society of Arts. He took an active part in the organization of the scientific apparatus at the South Kensington Museum in 1876, having superintended the collection and dispatch of the Natal collections to the Great Exhibition of 1862. He also compiled the catalogue of the Natal Court at the Colonial and Indian Exhibition of 1886.

George Redford.

George Redford is chiefly remembered in connexion with sculpture. He was born in 1816, and was registrar of the Crystal Palace collection of sculpture in 1853–54; curator of the Art Treasures Exhibition in Manchester in 1857; and commissioner for the National Exhibition of Works of Art in Leeds in 1868. He was elected a F.R.C.S. in 1869, and published *A Manual of Ancient Sculpture with Illustrations and Chronological Lists*, in 1886. His son, George Alexander Redford, was well known for many years as the official examiner of plays.

The Bishop of Labuan and Sarawak.

Dr. Francis Thomas McDougall seems to have been the only English bishop who passed the examinations and was admitted a Fellow of the Royal College of Surgeons of England. His father was a captain in the 88th Regiment who was quartered at Malta at the time of his son's birth in 1817; his mother was a woman of strong evangelical principles, and the bishop during his life was able to use all his qualities, both inherited and acquired. He was a first-rate fighter, an excellent doctor, and a sincere divine. He entered as a medical student at King's College, London, in 1835; matriculated at Oxford from Magdalen Hall in 1839; was for a short time medical officer to some ironworks in South Wales, and married the sister of Bishop Colenso's wife. The ironworks failed, McDougall was ordained, served as a curate at Christ Church, Woburn Square, accepted a permanent post in the British Museum, repented, undertook mission work in Borneo, and was consecrated Bishop of Labuan in 1855. In 1862 he had an exciting fight with Malay pirates, and sent an account to the *Times*, in which, quite unostentatiously, he shows himself to have been a first-class fighting man, a surgeon, and a priest. Some exception was taken to the tone of his letter by the "unco guid," for he says: "My double-barrelled Terry's Breechloader, made by Reilly, New Oxford Street, proved itself a most deadly weapon from its true shooting, certainty, and rapidity of fire. It never missed fire in 80 rounds, and was then so little fouled that I believe it would have fired 80 more with like effect." Dr. Tait, Bishop of London, when he next met McDougall, told him dryly that when there was occasion for another letter of a similar character it would be better if he let his wife write it for him.

After resigning his bishopric in 1868, McDougall became vicar of Godmanchester in Huntingdonshire, and afterwards a canon of Winchester, archdeacon of the Isle of Wight, and rector of Mottistone with Shorwell, where he is still

* Read in the Section of the History of Medicine at the Manchester meeting of the British Medical Association on Friday, July 26th, 1929.

remembered as a small, somewhat portly person who could occasionally be prevailed upon to tell of his early experiences when he had demonstrated anatomy at King's College. He died in 1886.

Alfred Smee.

Alfred Smee was but little interested in surgery, though the directors of the Bank of England created the post of surgeon especially for him in order to use his great scientific knowledge entirely in their service. His father was accountant-general to the bank, and Alfred was educated at St. Paul's School, at King's College, and at St. Bartholomew's Hospital. He devoted himself from an early period to the study of chemistry and physics, and had he lived now he would have been a distinguished electrical engineer. "Smee's battery" of zinc and silver in sulphuric acid still recalls his name. It was largely employed for trade purposes, and gained the Isis gold medal at the Royal Society of Arts. In 1842 he invented a durable writing ink, and in 1854 he perfected a system of printing the cheques and notes. Certain modifications were also introduced into the manufacture of notes to prevent and render it impossible any longer to split them. His communication on "The new Bank of England notes and the substitution of surface printing from electrotypes for copperplate printing" was read before the Society of Arts in 1842. He was also much interested in electro-biology, and was a pioneer in the territory of electrical physiology. He was one of the founders of the Gresham Life Assurance Society and of the Accident Insurance Company. Although his medical work was subordinated to other issues, his acumen enabled him to carry out improvements in the details of everyday surgical practice. Whilst he was still a student he invented that method of making splints which was largely used under the name of "gum and chalk" until they were superseded by "Croft's splints," and he was quick to turn to account the physical properties of guttapercha. He also employed electrical means to detect the presence of needles impacted in different parts of the human body.

And so one might continue with many others. They were honoured in their generations and were the glory of their times, although they were never surgeons, for they be of them that have left a name behind them that their praises might be reported.

THE BOARD OF CONTROL.

Fifteenth Annual Report.

In their annual report[1] for the year 1928 the Commissioners of the Board of Control express their regret that legislation to give effect to the recommendations of the Royal Commission on Lunacy and Mental Disorder has not yet materialized. This postponement is all the more regrettable inasmuch as the poorer classes must continue to be denied facilities for voluntary treatment in the early and hopeful stages of mental disorder which are open to those more fortunately circumstanced. The Board hopes, however, that it may be possible to introduce legislation at an early stage in the next session of Parliament.

Mental Disorder.

The incidence of fresh cases of mental disorder during the past year as notified under the Lunacy Acts has been slightly above the average for the last five years—2,787 cases as against 2,149. There appears, however, to be no ground for the suggestion that the stress of modern life has resulted in an abnormal increase in insanity. The average increase of approximately 2,000 a year in the number of patients under care is due very largely to increased longevity, both in mental hospitals and among the population generally.

The Commissioners regret that the general recovery rate has remained practically constant over a long period of years, notwithstanding the undoubted success which has attended the treatment of general paralysis by induced malaria. This disease is present in some 6 per cent. of the total admissions, and in as many as 11 per cent. of the male admissions, and has a yearly death rate of 1,500 persons, so that its alleviation or cure is a matter of very considerable moment.

In an exhaustive report[2] by Surgeon Rear-Admiral Meagher, one of the Board's inspectors, cases treated by the new method in England and Wales from 1922 to 1927, numbering 1,500, were taken into account and contrasted with numbers of untreated cases in the same period. The results indicated that the treatment, especially when applied in the early stages, is a most encouraging advance, and definitely offers hopes of improvement which could not be expected without it.

Work of Mental Hospitals.

Steady progress is recorded in the process of hospitalization. From the point of view of humane treatment, the Board cannot speak too highly of the way in which mental hospitals are conducted. From the scientific point of view, however, the Board considers that much more might have been accomplished in many hospitals if there were a larger medical staff and a more generous provision of laboratory and other therapeutic resources.

Ultra-violet rays and other forms of light treatment are now being employed in a number of mental hospitals, but while good results have been claimed in some cases the present methods of applying those treatments are largely empirical. The Board welcomes the attention that this matter is receiving from a committee of the Medical Research Council and the steps which are being taken to associate certain mental hospitals in a definite scheme of research. With regard to all new lines of treatment it is highly desirable that hospitals should pool their experience; but this can only be done if the results of experimental methods are carefully and scientifically noted.

In deploring the ultra-conservative policy pursued by many visiting committees, the Board points out that the public generally, and in particular the patients' relatives, will never regard mental hospitals as hospitals in the true sense until they are satisfied that vigorous effort directed to the individual patient is being made to effect a cure.

The Nursing Staffs.

With respect to nursing personnel, gratifying progress is recorded in the provision of nurses' homes. This is welcomed not only because fresh accommodation for patients is thus released, but still more because of the importance of securing for the nursing staff restful and comfortable surroundings. Mental nursing is an arduous and exacting occupation, and young nurses cannot be expected to combine with their duty in the wards the theoretical instruction which is now demanded of them unless their hours off duty are quiet and uninterrupted.

It is regrettable that the training of mental nurses is still in an unsatisfactory and unsettled condition, owing to the continuance of two sets of examinations and alternative certificates based upon an almost identical curriculum. The Board would cordially welcome any agreement between the General Nursing Council and the Royal Medico-Psychological Association which would secure a unified examination system.

Treatment and After-Treatment.

Gratifying results have been obtained in some mental hospitals by the development of occupational therapy, and it is recommended that the appointment of occupation officers be more generally adopted. It is increasingly recognized that there are many apparently unemployable patients who, in the hands of staff trained in teaching handicrafts of various kinds, can be occupied with great benefit to themselves if sufficient care is taken to select the particular kind of occupation best suited to the patient's mental condition.

The Board notes with pleasure the increasing number of centres for out-patient treatment which are being opened, generally in conjunction with a local voluntary hospital

and with the co-operation of the medical superintendent. The Board wishes to see the number of these largely increased, and appeals for the co-operation of the press in emphasizing the irreparable harm which may be done by postponing any attempt to seek treatment until concealment is no longer possible and until the patient has to be certified.

With regard to those who are discharged from mental hospitals, and who so often find the transition from the ordered and sheltered life of the hospital to the stress and competition of the outside world too exacting, the Board pays a tribute to the excellent work accomplished by the Mental After-Care Association.

Improvements in the Mental Hospitals.

The linking up of a number of mental hospitals with medical schools is viewed with approbation. Such an arrangement cannot but prove mutually beneficial. It makes available to the mental hospital patients the services and advice of operating surgeons and other specialists; it is stimulating to the medical staff of the general hospital, and helps them to realize that psychological medicine is not a subject to be studied in isolation, but is a part of medicine as a whole. Nothing could be worse for psychological medicine than any tendency to divorce it from other branches of medical study. Closer co-operation between mental hospitals and general hospitals, particularly teaching hospitals, will be to the benefit of all concerned.

The Board has followed with interest the scheme of study tours of foreign hospitals organized by the Royal Medico-Psychological Association. It is believed that the mental hospitals in Great Britain will stand comparison with those of any other country; but it would be foolish to suggest that there is nothing to be learnt from a study of Continental methods.

The need for additional beds in the county and borough mental hospitals continues to be acute. There is practically no margin of vacant accommodation anywhere, and in not a few cases there is now overcrowding of both day and night space. A number of buildings suitable for the accommodation of the quieter protracted type will probably be available under the new Local Government Act; but such relief will be merely temporary, and the Board urges the authorities not to postpone any effort to meet their problems, and to take into account their probable requirements for a term of years.

Statistics for the Year.

On January 1st, 1929, the number of notified insane persons under care in England and Wales was 141,080, an increase of 2,787 during the preceding year. The percentage distribution of the sexes—males 43.9, females 56.1—was practically unchanged. Private patients numbered 14,636 (males 8,549, females 6,087). Included in this number are 5,402 "service" and "ex-service" patients. Rate-aided patients on the same date numbered 125,534 (males 52,753, females 72,781), or 89 per cent. of all the notified insane. Criminal patients numbered 910 (males 687, females 223), an increase of 17 during the year.

Direct admissions during the year numbered 22,377 (males 10,002, females 12,375) of which 92.8 per cent. were admitted into county and borough mental hospitals; this number was 484 more than in 1927. First admissions numbered 17,766 (males 8,231, females 9,535) or 79.4 per cent. of all the direct admissions.

The number of persons discharged was 10,386 (males 4,236, females, 6,150). Of these, 6,901 were discharged as recovered, yielding a recovery rate, calculated on the direct admissions, of 30.84 per cent. (28.21 for males, 32.96 for females). Deaths numbered 8,769 (males 4,372, females 4,397). They were 542 fewer than in the preceding year; and the death rate was 7.31 per cent. of the daily average number resident.

MENTAL DEFICIENCY.

The Commissioners of the Board of Control feel it incumbent on them to repeat that the subject of mental deficiency is closely related to that of mental disorders, and that many of the questions involved are but different aspects of what is in reality one problem. The Board desires to see a more frequent use made of Sections 28 or 66 of the Mental Deficiency Act of 1913, under which it is possible to create one committee for the discharge of duties under both Acts. This would enable all matters in the area which were specifically related to mental health to receive unified consideration.

Little progress has been made during the year to meet the shortage of accommodation for mental defectives. This delay is to be ascribed to the introduction of the Local Government Act causing local authorities to defer action until they saw what accommodation for mental deficiency and other health services would become available. Some authorities have shown an inclination to defer expenditure on the ground that they are no longer receiving a 50 per cent. grant; but as the Minister of Health has repeatedly pointed out, the new block grant includes a substantial amount of new money to provide for the development of their services, and local authorities have no justification for postponing necessary expenditure on the ground that they are not receiving adequate assistance from the Exchequer.

In the opinion of the Board, the Local Government Act should result in a very great improvement in the provision for this unfortunate section of society. Hitherto, mental deficiency committees have had, in general, no duties in relation to defectives in receipt of any form of Poor Law assistance. Under the Local Government Act for the first time unified control becomes possible, and all defectives in the area, other than those dealt with by the local education authority, may be brought within the scope of the mental deficiency committee.

Marriage of Mental Defectives and Sterilization.

The Board is of opinion that sterilization will not obviate the need of institutional treatment for large numbers of mental defectives. So far as the low grade cases—idiots and imbeciles—are concerned, the need for institutional treatment is obvious; but with regard to the feeble-minded, who form approximately three-quarters of the whole number of mental defectives, it is not sufficiently understood that the great majority are incapable of managing themselves. The greater number of defectives cannot support themselves, many cannot resist criminal impulses, and others, though not actively dangerous, are a menace to the community, because they have no idea of truth or social obligation, and because they cannot keep themselves clean or observe the simplest rules of personal hygiene. Such anti-social tendencies and habits, states the Board, are not to be cured or even lessened by sterilization, and as the provision of institutional beds is far below even the most conservative estimate of present needs, it hopes that no local authority will relax its efforts because of any fallacious promise of what sterilization might achieve.

The Board holds that it would be a valuable safeguard if the marriage of defectives, whether under order or under supervision, could be prohibited by law. A definite prohibition of the marriage of defectives would prevent unions which are socially disastrous and would make it much easier to secure the protection of young defectives under supervision or guardianship or on licence by bringing home to the public conscience the antisocial character of any overtures towards persons definitely stamped as incapable of valid marriage.

Statistics for the Year.

The number of mentally defective patients on January 1st, 1929, was 45,415 (males 22,803, females 22,612); included in this total are the cases under statutory supervision, which numbered 19,606 (males 10,541, females 9,065).

During 1928 there were increases of 95 in State institutions, of 741 in certified institutions, of 556 in Poor Law institutions, of 9 in approved homes, of 245 among those under guardianship or notified, and of 1,712 under statutory supervision, while the number in certified houses decreased by 6, making a total net increase of 3,352 patients under care.

British Medical Journal.

SATURDAY, OCTOBER 5TH, 1929.

TEAM WORK IN RESEARCH.

The methods of large-scale organization, so characteristic of the age we live in, may be seen operating in the field of scientific investigation as fully perhaps as in any other department of human activity. In this period, characterized by a developing collectivist ideology, scientific research indeed, like art, would at first sight appear to be the last refuge of individualism. Yet there is a sense in which it is true that all scientific investigation is collective. The greatest individualist among scientific workers can build only on a foundation others have laid before him; through the medium of scientific journals and learned societies he must meet and receive stimulation from others engaged in work related to his own; in a thousand ways he must use knowledge which others have gained in the past or are at the moment collecting round him; and in the end his own contribution is but an instalment which must be merged in the unending serial story of man's discovery of the universe. The scientist of popular imagination—the isolated individual ploughing his lonely furrow through an uncharted wilderness—has indeed his counterpart in reality. But his loneliness is an illusion; his wilderness is the meeting place of an international conference in perpetual session.

There are, indeed, vital differences between collective research undertaken in this loose and undeliberate manner and collective research planned and organized by groups of scientists working in teams. In every new territory invaded by science the independent pioneer has blazed a trail along which others have had to follow. It would seem as though at every stage, as science makes its halting progress, there is a period, perhaps only a moment, when the direction of the next step is uncertain, when the difficulties are hardly realized, and the problems yet inadequately formulated. It is a period of reconnaissance, when only the loosest organization, giving the greatest scope for independence and originality, is likely to ensure success. But after that, the more carefully planned and directed the advance the better. Independence and team work in scientific investigation are complementary to each other; both are necessary for the advancement of knowledge.

Once the need for organization is admitted it is inevitable that a demand should arise for bigger and better teams. In the field of medical research the unit may be the hospital; or, as at St. Andrews, the bulk of the practitioners in a district; or, as in the collective investigations undertaken by the British Medical Association, members of the medical profession throughout the whole country. It will be recalled that the latter team—surely the largest that has ever been brought together for the advancement of medical knowledge—last year made collective investigations of the treatment of varicose ulceration and the after-effects of gastro-enterostomy. This year, encouraged by the success with which these inquiries were attended, the Council has decided to invite a similarly constituted team to investigate the incidence of cancer and its history after treatment. As before, the success of the inquiry will depend on the patient and enthusiastic co-operation of members of the Association in all parts of the country, on the care with which they make their observations, and the accuracy with which they record their findings. Above all, it will depend on the precision with which the questions to which an answer is required are defined. The inquiry is to be limited to carcinoma of the breast, cervix, rectum, and tongue, and its object is to obtain information about the previous history of patients suffering from these forms of carcinoma; the actual evolution of the disease itself, especially of the first symptom which called attention to it; the result of any treatment which may be undertaken, and the duration of the disease both when treated and when untreated. On these matters it is believed that the general practitioner is in a far better position to make the necessary personal observation and to supply reliable information than is the operating surgeon, under whose care the patient may come only for a short time. The inquiry will cover a period of one year, and practitioners participating in it will be asked to keep records, on specially printed forms, of all cases of the conditions under investigation which come to their notice during this period. The questions to which answers are required have been formulated with great care; they are precise, and have been designed to elicit all the information relevant to the inquiry, while imposing a minimum of clerical labour on the practitioners sharing in the work.*

We have mentioned some of the conditions whose fulfilment we believe to be essential to success. There is yet another: the inquiry is in large part statistical, and to reduce the chances of error the net must be spread as wide as possible. Every Division of the British Medical Association should make it its duty to ensure that every one of its members in a position to do so shall take part in the investigation; in the fight against disease God is on the side of the big battalions.

THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

We offer a cordial welcome to the British College of Obstetricians and Gynaecologists, which was incorporated on September 13th and held its first council meeting in London last week. The proposed Memorandum and Articles of Association of the new body were described in an article in our issue of March 9th (p. 462); the wording of these has now been amended in certain respects, but as they stand they are still admirably adapted to serve the purpose for which the College was established—namely, to encourage the study and improve the practice of obstetrics and gynaecology. The officers and council, whose names are printed elsewhere in this issue (p. 627), are thoroughly representative, and under their guidance the new College may be trusted to use to the best effect the powers it has been granted. Of special interest are those clauses in the Memorandum of Association which deal with the functions of the College in relation to the examination of candidates for admission to the *Medical Register* and the granting of special diplomas. According to these clauses the College will, if invited by the authorized teaching and examining bodies, co-operate in the examination of candidates for admission to the *Medical Register*. Furthermore, it may,

* Secretaries of Divisions have been requested to forward to the Head Office the names of those who are willing to help in this new collective investigation. Members of the Association desiring to take part who are not approached through their Divisional machinery should apply to the Medical Secretary for the special forms on which the required particulars are to be recorded. We hope to publish shortly the questionaries relating to the various forms of cancer upon which information is desired.

either alone or in co-operation with authorized teaching and examining bodies, grant to registered medical practitioners diplomas or other equivalent recognition of special knowledge in obstetrics and gynaecology. Diplomas granted independently by the College, however, will not of themselves confer any legal qualification to practise, and will embody a statement to the effect that they have been issued by the authority of the College only. If and so long as the College, on the joint invitation of the Royal College of Physicians of London and the Royal College of Surgeons of England, co-operates with them in holding an examination and granting a diploma in obstetrics and gynaecology, it will not independently grant a diploma or other equivalent recognition of special knowledge in these subjects, though this provision will not debar it from holding joint examinations and granting joint diplomas with any other authorized teaching or examining body.

The College has shown in its by-laws that it will take no light view of the standard of education and experience that must be attained by those who aspire to its fellowship or membership. Every applicant for membership will be required to submit evidence of having held one or more of the following appointments: (*a*) for at least six months, a resident post in a maternity hospital or the maternity department of a general hospital, and for at least six months in a gynaecological hospital or gynaecological department of a general hospital; (*b*) for at least one year a resident post which combines obstetrics and gynaecology; (*c*) for at least one year a post on the honorary staff of a hospital which combines obstetrical and gynaecological practice; (*d*) for at least six months a resident post in an obstetrical hospital, and for at least one year the post of registrar in a gynaecological hospital or the gynaecological department of a general hospital; or (*e*) for at least six months a resident post in the obstetrical and gynaecological wards of a general hospital, followed by at least a year as registrar in a similar department. The applicant will, in addition, have to submit a fully documented record of fifty consecutive obstetrical cases attended personally, and twenty consecutive gynaecological operations which he or she has performed; and with at least one of the obstetrical and one of the gynaecological cases a review of the literature will be required as well. Applicants will only be admitted to the membership if their names are entered on the British *Medical Register* or on the register of duly qualified practitioners of a British dominion or dependency; and at the meeting at which any name is submitted for election a majority in the candidate's favour of two-thirds of the members of council present will be required. The council may from time to time elect to the fellowship such members of the College as it judges to have advanced the science and art of obstetrics and gynaecology; it may furthermore elect to honorary fellowship obstetricians and gynaecologists of renown, distinguished members of the medical profession, and other eminent persons not necessarily members of the medical profession. Everyone admitted to the College as fellow or member will be required to subscribe to the following declaration: "I solemnly affirm that I will at all times maintain the welfare and dignity of the College, faithfully obeying in the spirit as well as in the letter the Articles and Regulations, and submitting myself to the lawful authority of the Council. Furthermore, I pledge myself in the practice of the art of obstetrics and gynaecology ever to have regard to the honour of the College and to the welfare of the State."

The innovations foreshadowed in those clauses of the Memorandum which deal with the granting of diplomas and other equivalent recognition of special knowledge of obstetrics and gynaecology are of far-reaching importance; we may hope that no step towards putting them into effect will be taken except after the fullest consultation between the College and the established teaching and examining bodies. We are not disposed to underestimate the difficulties that have yet to be overcome; nor do we imagine that the College, exclusively occupied with obstetrics and gynaecology, will always find itself in accord with the teaching and examining bodies whose interests are necessarily wider. Our hope that harmony will be reached and conflicting views will be adjusted is based on the faith that everyone concerned is animated by the single ideal of raising as high as possible the level of medical practice in all its branches.

GROUP TEMPERATURE RECORDING.

In certain circumstances medical officers are called upon to take the temperatures of a large number of patients in a small space of time, and the use of the ordinary clinical thermometer makes this a lengthy and tedious procedure. By a large number of patients is meant, of course, many more than the usual content of the average hospital ward, where a nurse armed with, say, three clinical thermometers very quickly gets round. In the course of investigating the temperatures of native mine labourers in South Africa with the idea of quickly detecting those showing abnormal temperatures for further examination, Sir Spencer Lister found that the use of the ordinary mercurial thermometer was impracticable. He has therefore devised, with the help of Professor A. V. Hill in London, an electrical apparatus for this purpose which he has recently described in detail.[1] The principle of the electrical thermometer is similar to that already applied to the construction of thermometers for other than clinical purposes, and depends upon the "thermocouple," the action of which, it will be remembered, is due to the production of a thermo-electric force when the junctions of different metals in an electric circuit are at different temperatures. In the apparatus used by Sir Spencer Lister a "battery" of fifteen such thermocouples is employed. The fifteen "cold" junctions are immersed in a thermos flask in which the temperature is kept constantly at 98.4° F. The fifteen corresponding "hot" junctions are hanging free in the air, or in disinfectant if so desired, and may be situated at any convenient distance from the "cold" junctions. These free-lying "hot" junctions are placed in the mouths or axillae of the subjects whose temperatures are to be recorded. The "hot" and "cold" junctions are wired in circuit with a dead beat moving-coil galvanometer with a reflecting mirror. A switchboard is included in the circuit so that each thermocouple can be separately connected with the galvanometer by moving the necessary switch. The galvanometer mirror reflects a beam of light on to a calibrated scale on which the temperature of the individual in contact with the "hot" junction can be rapidly read. In practice fifteen individuals hold the "hot" junctions beneath the tongue and the investigator rapidly closes the necessary switches in turn, noting any deviation from normal on the calibrated scale. As soon as the subject at number one thermocouple has had his temperature read he moves away, the "hot" junction is placed in disinfectant, rinsed, and the next subject (that is, number sixteen) takes his place. By the time the subject at number fifteen is finished a new batch of subjects is in position and the process is rapidly

[1] *Journ. of the Med. Assoc. of South Africa*, 1929, iii, 155.

and easily repeated. Besides detecting quickly all patients with abnormal temperatures, the exact degree of abnormality can be read upon the calibrated scale, but this naturally takes more time. The apparatus is at present in use at the South African Institute for Medical Research, Johannesburg, and with inevitable improvements towards greater compactness and portability it may prove a very useful instrument for recording temperatures in a wholesale fashion.

EPIDEMIC ENCEPHALITIS AND PREGNANCY.

THE comparatively infrequent association of these two conditions has not in this country attracted much attention, and not until recently has any important study of the subject appeared in English medical literature. Even now the amount of first-hand material which Dr. Frederick Roques has been able to use in his recently issued monograph, *Epidemic Encephalitis in Association with Pregnancy, Labour, and the Puerperium*,[1] of which a brief notice appeared in our issue of March 23rd (p. 560) is somewhat slight, as the author himself admits. But Dr. Roques reinforces the evidence provided by the 40 cases coming *more or less directly under his own observation* with evidence derived from some 170 case records of other clinicians and compilers, both at home and abroad. Among such records are the list of cases published by the Ministry of Health in 1922[2] and an earlier list compiled by Dr. Ricardo Jorge in 1921,[3] which refers mainly to Continental cases. Dr. Roques has made the very most of his subject, the many facets of which he skilfully presents in turn for detailed examination. Dealing first with the influence of pregnancy upon epidemic encephalitis, he concludes that pregnancy does not increase susceptibility to the disease, nor does it apparently alter or aggravate the symptoms of an acute attack; parity has little, if any, effect upon the course of the disease. The case mortality, according to British experience, is not affected adversely, but Continental writers consider that the fatality rate is higher in pregnant women than in others. The influence of labour is variable. As regards the effect of an acute attack of epidemic encephalitis upon pregnancy, there is again some difference of opinion between English and foreign observers. The former consider that, as a rule, the prospects of the pregnant woman are no worse than those of others, while the latter find that gestation is interrupted in a large number of cases. Labour itself is said to be less painful than under normal conditions, while the puerperium is usually uneventful, though occasionally retention of urine has been recorded. As to the child. Dr. Roques finds that the combined foetal and infantile mortality varies directly with the stage of gestation and the maternal issue; the most common causes of foetal mortality are maternal death before delivery in the earlier months and prematurity in the later months; but provided pregnancy goes to full term, and as far as the acute phase of the disease concerns the mother, the child's chances are generally good. Moreover, infants born of such infected mothers and who survive the first few weeks of life usually escape altogether. The author is satisfied that infection through the mother's milk is highly improbable, and, while considering that the term "encephalitis epidemica neonatorum" has become justified, he finds no clear evidence that maternal infection of newly born infants occurs frequently, if at all. This exemplifies once more the apparently slight infectiousness of patients suffering from epidemic encephalitis; for, assuming that the virus of the disease exists in the patient's oral and nasal secretions, it is hard to conceive a relationship more conducive to the transference of infection than that established between a mother and her newborn babe. But possibly, as the author suggests, we have here another feature of resemblance between epidemic encephalitis and syphilis in that the infected mother cannot harm her own child after birth. On the other hand, there is evidence on pathological and clinical grounds, as well as from experiments with rabbits, that placental transmission of the virus is possible, and there is reason to believe that three or four cases of congenital encephalitis lethargica have been correctly reported as such. For his conclusions concerning the interactions of Parkinsonism—that is, chronic epidemic encephalitis—and pregnancy, Dr. Roques relies on the evidence furnished by cases observed in this country. He finds that, while pregnancy does not increase the chances of becoming primarily infected with epidemic encephalitis, those pregnant women who are attacked are more likely to develop Parkinsonism than women not in that state: that existing Parkinsonism is frequently aggravated as a result of pregnancy, the aggravation occurring usually either early in gestation or shortly after the confinement. On the other hand, Parkinsonism has no malign influence on pregnancy, labour, or the puerperium, nor does it cause sterility. *Children born of Parkinsonian* parents are almost always healthy, and apparently remain so.

METHYL CHLORIDE POISONING.

TOXIC effects due to the inhalation of small quantities of gases of various kinds have become sufficiently widespread to constitute an important industrial problem. Although, owing to their more extensive use in industrial processes, compounds in the benzene or aromatic group have been more closely studied, attention has also been directed to the aliphatic hydrocarbons, which have an increasing use as refrigerators and as solvents for grease and rubber. The halogen derivatives of the aliphatic hydrocarbons appear to be more active than the corresponding hydrocarbons themselves, although the toxicity depends, not on the action of the halogen, but on that of the entire molecule. The inhalation of these gases, especially if prolonged, causes degenerative changes in the heart, liver, and kidneys, and may also lead to permanent lesions in the central nervous system. The monohalogen derivatives of methane appear to become decomposed in the body into methyl alcohol, and, as this substance tends to accumulate in the tissues, they may therefore give rise to severe destructive lesions. The physiological effects of trichlormethane (*chloroform*) and tetrachlormethane (*carbon* tetrachloride) have been very extensively studied, the former on account of its anaesthetic action, the latter because it is used on a large scale in rubber works (as a solvent), in the process of dry cleaning, and as a fire extinguisher. On the other hand, comparatively little attention has been paid to the monochloride or methyl chloride, this product having had but a limited use in industry. In recent years, however, with the advance of mechanical refrigeration, toxic gases of various kinds have been experimented with, and methyl chloride is now commonly used in domestic refrigerating plants, especially in America, and has caused a considerable amount of illness and a number of deaths. It is stated that in one city alone methyl chloride is in use in 75,000 domestic refrigerators. The gas is free from any marked odour or irritating effect, and therefore a small leak in the apparatus may pass unnoticed for long enough to permit a definite toxic effect to occur. According to Drs. Kegel, McNally, and Pope,[1] who record a series of interesting observations on the toxic effects of methyl chloride, this gas during the past year has been responsible in Chicago alone for twenty-nine cases of poisoning with ten deaths. The clinical picture is fairly characteristic—the outstanding symptoms being drowsiness,

[1] *Journ. Amer. Med. Assoc.*, August 3rd, p. 353.

mental confusion, coma, nausea, and vomiting—but if a history of exposure to the gas is not forthcoming a diagnosis of food poisoning or epidemic encephalitis is frequently made. The blood picture is that of a primary anaemia, and urinary examination may show the presence of formic acid, diacetic acid, and acetone. The sequels of methyl chloride poisoning are likely to be serious, their cause, as mentioned above, being destruction of nervous tissue by the accumulation within the body of methyl alcohol. In this country domestic refrigeration is still comparatively rare, and in the larger installations such compounds as sulphur dioxide and ammonia are more commonly used, but in any future development the noxious effects of many of the commonly used gases should be kept in mind.

BINOCULAR VISION.

BINOCULAR vision is perhaps the highest physical possession of man. Without it he would never have been the cunning workman that he is. To-day, more than ever, is this capability of value to him in his conquest of the air. Safety in landing is determined more by the visual judgement of the pilot than by any other factor. Lieutenant Commander N. M. S. Langlands of the Royal Navy has made a series of most elaborate and ingenious researches into the qualities and quantitative reactions of binocular vision.[1] The first recorded measurements of binocular acuity were made by von Helmholtz in 1896; he used three vertical needles, the centre one being movable. He could "with perfect certainty" correctly estimate a movement of half a millimetre out of the plane of the wing needles; he concluded that the acuity was 60.5 seconds. The measurement has since been found to be too high. In all experiments the binocular acuity is determined by the minimum resolvable difference in depth, and is measured by the smallest difference of binocular parallax which can just be appreciated. It is necessary that the test objects or their images should be at some considerable distance, so as to exclude the possibility of judgement of difference of depth by variation of accommodation. Commander Langlands's new tests are of a highly technical order, and they show great ingenuity in the adaptation of his instruments. The accuracy of his observations seems certain. He found that *with an increase of the field of vision there was an increase* in the acuity of binocular vision. Binocular acuity did not always go with good form sense; both appeared to improve with practice, but sometimes the form sense seemed to be poorer than the binocular acuity. Duration of illumination of the tests varied the acuity appreciably. The acuity obtained in some of the experiments involved some reconsideration of the theories of visual perception. Hering explained binocular acuity as involving an integral number of cone widths in the retinae. From a consideration of stereoscopic and entopic phenomena, Fortin has thought that the cone is too large to function as the ultimate receptor, and he suggested that the receptors were bell-shaped elements, which he claims to have discovered between the external fibre layer and the internal nuclear layer. Langlands, the author of the latest researches, has outlined a theory of binocular vision based on the photo-electric theory of vision. Light falling on the photo-chemical liquid between the cones causes energy, in the form of an emission of electrons, to flow out from the region of incidence and to stimulate the neighbouring cones. The perceptual pattern of the object is derived from the flow of energy from the cones near the physical retinal image. In some of the tests so fine an acuity as 1.5 seconds was obtained, and this would suggest that corresponding elements are interconnected, so that the energy flowing from the two elements can be compared.

NATIONAL ASSOCIATION FOR PREVENTION OF TUBERCULOSIS.

RATHER more than three years ago a special appeal for £100,000 was launched by the National Association for the Prevention of Tuberculosis. At the thirtieth annual general meeting, on July 22nd, it was announced that the total amount collected was £110,941. In the annual report of the association for 1928 there is an account of the way in which this money is being used. Four medical commissioners have been appointed to deliver lectures and engage in general propaganda activities; three motor vans have been equipped with interesting exhibits, including cinematograph apparatus; illustrated lectures are being given in many parts of England and Scotland, and care committees have been established for the supervision of tuberculous patients and their families. Grants are being made towards the establishment of workshops for tuberculous patients and also towards the Burrow Hill Sanatorium Colony. In special individual cases, where there is some need which is not covered by the ordinary tuberculosis machinery, financial assistance is given. Commenting on these various activities, attention is drawn in the report to the valuable services rendered by the medical commissioners, and a detailed account of their work, including a list of the places visited, is contained in an appendix. As an outcome of the educational campaign a scheme for more intensive propaganda was launched in Scotland with the joint support of the National Association, the Scottish Branch of the British Red Cross Society, the Royal Victoria Hospital Tuberculosis Trust, and the Scottish Branch of the Queen's Institute of District Nursing. Two commissioners were appointed for special nursing duties also, and, after a pioneer caravan tour had been made through the Western Highlands in the summer of 1927, it was decided that these commissioners should work in Inverness-shire and Ross-shire, with special reference to the provision of instruction in the prevention of tuberculosis. At the Burrow Hill Sanatorium Colony an experimental scheme is in operation for providing treatment and technical training for lads between the ages of 14 and 19. Reference to the work of this institution appeared in our issue of March 23rd (p. 570). Dr. McPhail, the assistant medical superintendent, has made an extensive tour in England, explaining to public health authorities the principles laid down for the successful running of this most valuable colony. Two useful appendices to this annual report give lists of cinematograph films for public exhibition and also of lantern slides relating to the prevention and treatment of tuberculosis. The fifteenth annual conference of the National Association will be held from October 10th to the 12th next, in the Connaught Hall, Newcastle-upon-Tyne. After the formal opening of the conference a sociological survey of tuberculosis on Tyneside will be reported. The subjects announced for discussion include: the factors that produce adult pulmonary tuberculosis; the combined treatment and technical education of tuberculous youths; the provision of instruction in tuberculosis for undergraduates and medical officers; methods of local propaganda; and dentistry in relation to tuberculosis.

MODERN CIVILIZATION.

MR. W. E. D. ALLEN, M.P., writing about the Russian Soviet Republics, has well said that "the fundamental problem of the modern world is the adjustment of the mind and the emotions of men to the changing physical conditions of the new mechanistic age. Social organization has not proceeded so rapidly as industrial development, and where conditions of life have been static and the human mind has lacked plasticity, there the processes of transformation and adaptation have been characterized by the most violent shocks." Dr. Charles A. Beard, the

editor and introducer of a recently published symposium entitled, *Whither Mankind: A Panorama of Modern Civilization*,[1] speaks of an "inquisitive wondering about civilization" and an "anxiety about the values and future of civilization"; and there is no doubt that such wondering and anxiety is the increasing occupation of many minds. Any book whose declared purpose is pertinent thinking and a clarification of notions on these matters should be the subject of interested and respectful attention if its authors are of a status which entitles them to attention. There can be no doubt that the contributors to the volume which Dr. Beard has produced are of this status, and there can be no doubt either that they have together composed a remarkable book. The authorship and outlook are partly British and partly American, but there are included also essays by such men as Emil Ludwig and Hu Shih. The latter leads with a novel and thought-provoking chapter on "The Civilization of the East and the West," differentiating them by the facts that "Oriental civilization is built primarily on human labour as the source of power, whereas the modern civilization of the West is built on the basis of the power of machinery"; he maintains, nevertheless, that it is the former which is "materialistic" and the latter which is "spiritual," for "that civilization which makes the fullest possible use of human ingenuity and intelligence in search of truth in order to control nature and transform matter for the service of mankind, to liberate the human spirit from ignorance, superstition and slavery to the forces of nature, and to reform social and political institutions for the benefit of the greatest number—such a civilization is highly idealistic and spiritual." Similarly, dealing with the division of civilizations in terms of their time and not their place, Mr. H. W. van Loon claims the year 1769 as "the great milestone of mankind." On January 5th in that year James Watt patented his new machine. "It was on that day that the era of the deus ex machina came to an end and that the epoch of the homo in machinae commenced. It was on that day that man ceased to be a beast of burden and was given his first decent chance to become a human being." Such may be said to be the general outlook of the essays here collected, but this does not mean that all are in eulogy of the modern world. The chapter on "Education," by Everitt Dean Martin, for instance, is a very powerful and whole-hearted indictment of the American educational system. We hope and believe that the greater part of this chapter is wholly inapplicable to education in Great Britain: certainly if it is intended to apply, a formidable defence could be put up, though, as a warning, it is not negligible. The earlier part of Dr. C. E. A. Winslow's chapter on "Health" contains a brief but broad and useful survey of what modern scientific civilization has accomplished in this field; and, in considering some of its potentialities for the future, emphasizes the fact that "the modern public health movement is not based on autocratic dictatorship, but on democratic education of a free and intelligent people by the force of expert leadership," a statement which may be commended to the notice of some of those who just now are beginning, both locally and centrally, to administer health affairs in this country. No doubt particular essays in this volume—on "Business," "Law and Government," "War and Peace," "Religion," "Philosophy," "The Arts," "Literature," and so on—will be found of special interest to individual readers; but certainly among the most interesting, attractive, provocative, and stimulating are those on "Science," by Bertrand Russell, and on "Labour," by Beatrice and Sidney Webb. Neither of these should be missed by anyone who can delight in comprehensive and suggestive thought compactly and almost perfectly expressed.

OCCUPATIONAL THERAPY FOR CRIPPLES.

An international exhibition of handicrafts will be held at Exeter from October 30th to November 1st, under the auspices of the Devonian Association for Cripples Aid, supported by the Central Committee for the Care of Cripples and the International Society for the Care of Cripples in New York. At this exhibition will be assembled specimens of work by cripples, not only in all parts of this country, but in the United States of America and many European countries. The variety of the work shown, and the high degree of skill, technical and artistic, attained by craftsmen suffering from gross physical disablement are likely to come as a surprise to those without experience of what can be achieved by the carefully directed training of crippled persons. Even while orthopaedic treatment is still in progress the patient may derive great psychological benefit from vocational and occupational therapy; but the chief advantage comes later, when, equipped with a suitable trade, he leaves hospital fit to enter the labour market as an active and useful citizen. The trade, however, must be adapted to his physical condition; his employment in an unsuitable occupation may quickly bring about a relapse and undo the results of many months of treatment in a hospital. The exhibition at Exeter is intended to show how much even the limited amount of occupational therapy now available has accomplished. It is hoped, however, that it will serve to stimulate efforts to organize such therapy on a much larger and more generous scale than any that has hitherto been attempted. Proper organization would ensure that in training the disabled the needs of the labour market are taken fully into account. Dame Georgiana Buller, chairman of the Devonian Association for Cripples Aid, has done well to bring these important problems into focus.

ASSISTANCE FOR THE DEAF.

THE National Institute for the Deaf has rendered excellent service by compiling and issuing its handbook, *The Problem of the Deaf*.[1] The short title does not fully indicate the value of the book. It is not a piece of propaganda on behalf of the deaf so much as a full and well-documented "inquire within" upon everything that can concern the welfare of the deaf. Most specialists in disease of the ear know what to do for the advantage of their incurably deaf patients, and some members of education committees have this knowledge; but there are few general practitioners who do not feel somewhat at a loss how to assist such afflicted persons, and the general public are for the most part entirely in ignorance. In this book there are excellent accounts of measures for the prevention of deafness, on education of the deaf, on the teaching of lip-reading, on aids to hearing for those whose deafness is acquired, upon legal provisions for the assistance of the deaf, on welfare work, hospitals, special schools, and organizations for the assistance of the deaf. The deaf fall into two essentially distinct general classes, according to the history of their affliction: the deaf-born have to rely upon direct instruction by visual methods to develop language, but the deafened retain audible memories and continue to use them. These two diverse modes of language cerebration and their respective effects on language knowledge, mental development, and general outlook indicate wide variations in the conditions and needs of the two classes. Some 40,000 persons in Great Britain are deaf from birth, and are incapable of being benefited by the general provisions that exist for education. The State has recognized this disability, and spends yearly about £300,000 on their education to the age of 16 years; thereafter no provision is made save for some after-care work. Most of the work of assisting these persons falls to

[1] *The Problem of the Deaf.* A handbook of information on deafness, the deaf and dumb, and the deafened through disease or accident. Revised edition. London: The National Institute for the Deaf. 1929. (Pp. 96. 2s. net.)

voluntary societies. The deafened share with the born deaf the isolating silence of their common affliction, though its hardships are often more keenly realized because of the severance which it causes from accustomed habit and interests. They have the memories of their hearing days, and the abiding sense of their loss. Numbers lose their employment and live in enforced idleness. Few realize the hardships of the deaf; it is thought that this is the reason why so little is done to help the deaf, for it is doubtful whether more than £30,000 a year is voluntarily provided for work among them in this country. The book indicates what more could be undertaken for their assistance. The chapter on "Aids to hearing" is most valuable; there is an indication of the utility of general appliances, electrical and mechanical, with a warning against extravagant claims. The National Institute for the Deaf advises that the first step to be taken should be the obtaining of medical advice on the appliance likely to be of service; purchases should only be made from a firm willing to give advice about the merits of the proposed aid, and to refund the purchase money (less a small sum for expenses) should it prove unsuitable. The Institute is prepared to supply a list of firms which will undertake work on these terms. In its fifth annual report, which has been published recently, it is mentioned that a home for deaf women is being established in the North of England, and arrangements have been made, in conjunction with the National Institute for the Blind, for educating infant twins who are born both blind and deaf. Provision for the training of suitable candidates to be teachers of lip-reading is under consideration.

DETECTION OF MUSTARD GAS: INTERNATIONAL COMPETITION.

THE International Committee of the Red Cross, on the recommendation of a committee of experts which met at its instance at Brussels last year, has opened an international competition for the invention or discovery of a reaction capable of detecting minute quantities of mustard gas in air. It is laid down that the reaction must be characteristic for the gas, and sufficiently delicate to reveal a concentration as slight as 0.07 milligram of mustard gas in a litre of air. The competitor is required also to state whether the reaction is influenced by other chemical substances which might be mixed with mustard gas as used in war. The prize is 10,000 Swiss francs (rather more than £400), which may be awarded to one or divided between several competitors according to the value of the proposals submitted. The competition, which has just opened, does not close until December 31st, 1930. Before that date competitors should send in their entries to the secretary of the International Committee of the Red Cross (1, Promenade du Pin, Geneva) in the following manner: the name and address of the competitor should be placed in a sealed envelope, on the outside of which should be some distinguishing motto, together with a declaration that the reagent is the result of his own work. In a second sealed envelope bearing the same motto the detailed proposals should be given. The language used may be English, French, German, or Italian, but when the envelopes are opened at the beginning of 1931 the contents will be translated into French. Both the original texts and the translations will be examined by a jury, who will be aware only of the motto, not of the author's name. After the various proposals have been examined and assessed the envelopes containing the names will be opened, and the result of the competition published. The reagent will bear the name of its discoverer, but it will be the property of the International Red Cross; one of the conditions of the competition is that whatever apparatus is required shall be easy to construct and capable of being produced in large quantities at reasonable cost.

MEETING OF THE RADIUM COMMISSION.

AT the first formal meeting of the Radium Commission, which was held on September 27th, with Lord Lee of Fareham in the chair, it was provisionally agreed that loans of radium should be made only on terms which would recoup the Commission for expenses involved, and thus avoid the necessity of making calls on the National Radium Fund. Supplies of radium as placed at the disposal of the Commission by the Radium Trust will, pending distribution, be consigned for safe keeping to the National Physical Laboratory at Teddington, which will also undertake the testing and measuring of all consignments received from the manufacturers. The process of testing and measuring is necessarily slow, and it is therefore not anticipated that more than three grams at the outside will be available in suitable containers, ready for use, before the end of the year. The Commission hopes that a four-gram radium "bomb," to be used for intensive irradiation, may be secured on loan from the manufacturers for a limited period free of charge, and negotiations to this end are now in progress. An inquiry will be held by the Commission into the needs, equipment, and capabilities of institutions administering radium treatment, but at present no decisions can be arrived at as to the institutions to which radium may be loaned. The Commission agreed, however, on the principle that preference should, in the first instance, be given to centres where radium therapy can be combined with teaching and research. The offices of the Commission have been established at 5, Adelphi Terrace, Strand, W.C.2, and any communications should be addressed to the office secretary, Miss K. Griffiths. Dr. Sidney Russ, professor of physics at the Middlesex Hospital Medical School, has been appointed scientific secretary.

THE PANEL CONFERENCE.

THE provisional agenda has now been issued for the Annual Conference of Representatives of Local Medical and Panel Committees, to be held on Thursday, October 24th, at 10 a.m., in the Great Hall of the British Medical Association House, Tavistock Square, W.C., under the chairmanship of Dr. E. K. Le Fleming. Among the motions to be brought forward by the Insurance Acts Committee is the following recommendation, drafted on precisely the same lines as a resolution adopted by the Representative Body of the British Medical Association at Manchester in July last:

That the conference supports the Council of the British Medical Association in its effort to obtain amendment of Section 3 of the 1925 Dangerous Drugs Act, and recommends that heroin and its salts should come under the same conditions as morphine and its salts; also that the Council should on all possible occasions urge the Government not to enter into International Conventions involving medical questions until the opinion of the medical profession has been ascertained.

We print in the *Supplement* this week the supplementary report of the Insurance Acts Committee for 1928–29; the annual report appeared on August 24th. These two documents will form the basis of the proceedings at the Panel Conference. The final agenda is to be issued on October 17th.

THE Harveian Oration before the Royal College of Physicians of London will be delivered by Sir Wilmot Herringham, on Friday, October 18th, at 4 p.m., at the College, Pall Mall East, S.W.1.

THE seventh Lloyd Roberts Lecture has been arranged by the Royal College of Physicians of London for Thursday, November 14th, at 5 p.m. It will be delivered by the Right Hon. H. A. L. Fisher, LL.D., F.R.S., Warden of New College, Oxford.

Opening of the Winter Session.

MEDICAL SOCIETIES: THEIR ORIGIN AND VALUE.

Address to the Guy's Hospital Medical School

BY

SIR HUMPHRY ROLLESTON, BART., G.C.V.O., K.C.B., M.D.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE.

MEDICAL history seldom appeals to the student who has all that he can do to keep pace with the increasing demands of medical education, and to take his proper share of outside interests and healthy exercise. Indeed, study of the past may appear to be the province, with the advantage that it is also a wholesome corrective, of the senescent in the stage of anecdotage, whose experience forms the basis of their conversation and whose ambitions for to-morrow are of a strictly limited, conservative, and often largely negative character. On the other hand, those whose earthly pilgrimage commands a comparatively long vista of the recent rapid progress of science may plead that there is no better way of getting a sound grasp of present knowledge and of the probable future than by using the historical method and the picture it gives of past events and experience. In any event the beginning of the academic year is a time to look back as well as to the future.

Physic and the Guy's School.

It is impossible to think of the Medical School of Guy's Hospital without whole-hearted admiration for its traditions; for its Fathers in physic—Thomas Addison, Richard Bright, and Thomas Hodgkin; for Bright's initiation in 1842 of team work in the intensive study of renal disease; for other distinguished physicians, such as Samuel Wilks, Walter Moxon, James Goodhart, who were also foremost as pathologists; for the philosophic W. W. Gull; for F. W. Pavy, the active physiologist when an octogenarian; and for many others, including John Hilton, the surgeon, whose *Rest and Pain* mid-Victorian students were advised to read as more engrossing than the yellow-back novels of that period. The teaching of Guy's physicians has been freely given to generations of the profession in the text-books of Addison and Bright (1839); of Hilton Fagge, edited by P. H. Pye-Smith (1886); of Frederick Taylor (1890); continued until this present by E. P. Poulton and his collaborators; and, as an alternative attraction, in the textbook edited by J. J. Conybeare (1929). But great as are its traditions, Guy's does not live on its inheritance, for its *Reports*, so unobtrusively inspired by the senior physician, A. F. Hurst, are not only the oldest in London, but, like vintage wines, progressively improve. In yet another direction the school of Guy's Hospital has played a pioneer part—namely, in promoting the growth of medical societies and thus furthering medical education and progress, general understanding, and unity.

The Drawbacks of Medical Isolation.

In the past great advances in medicine have largely been due to individual effort without collaboration or much encouragement or financial assistance from outside sources; they have not come in a continuous stream, but in an interrupted fashion, depending on the irregular appearance of men with the necessary outstanding ability. It may be hoped that more general collaboration and team work will render the advance of medicine more regular and constant in the future than in the past. The attitude of the solitary worker is part of the individuality and independence of the members of our profession; unfortunately the accompanying lack of combination for mutual advantage, and on occasion for concerted action, has handicapped not only the profession as a whole, but its constituent members, who are thus apt to plough their lonely furrows while glancing askance at others as rivals rather than as familiar friends and helpful colleagues. It is perhaps not surprising that, accustomed to fight disease single-handed, the hermit-like doctor may not be devoid of antagonism to his professional brethren. It is, however, hardly necessary to labour the obvious value in the practice of our art and in the advance of our science of the human touch and the atmosphere of unity, peace, and concord which medical clubs, societies, and associations should foster and perpetuate. A medical club or society need not be, and probably seldom is, one for mutual admiration, but it should be one for mutual improvement and the furtherance of good relations—objects so inimitably set out in Sir William Osler's address "On the Educational Value of a Medical Society" (1903).

The Growth of Medical Clubs and Societies.

The first germ of medical clubs and societies may perhaps be found in the meetings, beginning about 1649 in Oxford, of an "Experimental Philosophicall Clubbe." As regards both its objects and its members, this was much the same as the Invisible or Philosophical College at Gresham College, London, out of which arose in 1662 the Royal Society, the *Philosophical Transactions* of which are, as R. T. Gunther points out, "an enduring memorial to the first scientific society in Oxford." Many, but by no means all, of the early members of these societies were physicians, such as John Wallis, Thomas Willis, William Petty, Francis Glisson, and George Ent, and in the science of that period medical problems took a far more prominent place than in these days of accumulated knowledge and the necessarily greater specialization of research.

It was in the eighteenth century that medical men as such began to unite in clubs and societies, and in Great Britain this example was set by Scotland; let us therefore gratefully acknowledge the influence of the students' great society—the Royal Medical Society—in Edinburgh, founded in 1734 and honoured by the grant of a Royal Charter in 1778. From it men like John Fothergill came south, and with fervid enthusiasm became moving spirits in starting medical societies in London. In the second half of the eighteenth century many medical clubs and societies saw the light in Edinburgh and London, some select, such as "The Society for the Improvement of Medical and Chirurgical Knowledge" (1783), others more catholic, like the "Lyceum Medicum Londinense" (1793), both inspired by John Hunter. Some of them had similar names, such as medical or physical societies, and thus there has been some confusion in tracing them. Among these eighteenth century societies two are of special interest here—the Guy's Physical Society and the Guy's Pupils' Physical Society.

The Physical Society of Guy's Hospital and the Medical Society of London.

The Physical Society of Guy's Hospital, with its name redolent of respectable antiquity dating from 1771, was composed of medical men in and near the hospital; its first president, William Saunders (1743–1817), was one of the original members of the Medical Society of London in 1773 and the first president of its offshoot—the Medical and Chirurgical Society—in 1805. The success of the Physical Society, though followed by flattering imitation, carried with it a penalty, for the competition of younger societies—the Medical Society of London (1773), the Medical and Chirurgical (1805), the Hunterian (1819), and the South London Medical Society (1832)—became so serious that in 1852 it ceased to be. Its declining years, however, were cheered by watching the activities of its offspring—the Pupils' Physical Society, which is confined to students of Guy's Hospital, members of the staff being eligible as honorary members only. As shown in the history of the Physical Society of Guy's Hospital, written by Sir William Hale-White and Dr. Maurice Campbell, the Pupils' Physical Society dates from 1830, and will therefore be able to celebrate its centenary in this academic year. It is a matter for sincere congratulation and justi-

fiable pride that, if the parent's and the offspring's lives be regarded as a continuous whole, the Physical Family, so to speak, of Guy's is the oldest medical society in London.

It is interesting, as showing the character of the men concerned, to glance at the connecting links between the Physical Society of Guy's Hospital and the present Medical Society of London, founded two years later, in 1773, by John Coakley Lettsom. Members of the senior society seem to have held out a helping hand to the junior; for Guy's is well represented in the picture painted in 1791 by Samuel Medley (1769-1857) of the twenty-two "founders" of the Medical Society, some of whom, however, were really men prominent in medical London at the time it was painted rather than responsible for the birth of the society. This well-known picture shows William Saunders; the much-beloved William Babington (1756-1833), one of the founders of the Hunterian Society in 1819, and, like his colleague Saunders, concerned in the formation of the Medical and Chirurgical Society in 1805; John Haighton (1755-1823), anatomist, physiologist, obstetrician, and mathematician; John Relph, physician to Guy's (1789-1804) and president of the Medical Society in 1785; and Robert John Thornton (1768-1837), a Cambridge Bachelor of Medicine (1793), lecturer on botany at Guy's, and a prolific writer on medical subjects.

Medical Clubs.

The evolution of a full-blown medical society can easily be traced. The embryonic stage is found in medical friendships and the gregarious nature of the human man; in due course the initiative of some energetic spirit creates a medical coterie or club, and meetings for the reading and discussion of papers follow. By expansion and systematic organization a medical club may give birth to a society with a more catholic membership: for example, the informal "Moorfields Club," which met in the house-surgeon's room for the discussion of ophthalmological cases and problems as far back as 1866, in 1880 took steps to establish the Ophthalmological Society. Sometimes, on the other hand, the club stage is short-lived, or is practically short-circuited, as, for example, in the formation of the Association of Physicians of Great Britain and Ireland.

Medical clubs differ from medical societies mainly in their less formal and more private character, in the more personal element, especially in the election of members, their limited membership, and usually in not possessing a library, which is such an essential asset to a medical society. A medical club is the organized outcome of a group of men working in unison; these clubs flourished long before the word team-work became popular in connexion with those engaged in original research, but the same fundamental principle that inspires the research workers is shared by clubs or small societies designed for mutual education. Medical clubs differ much in their objectives, the prominence of the scientific and social characters varying widely. Some starting with high educational intent have become more social and post-prandial, so that later the members are chosen rather for their clubbable attractions than because they are pale students. Such a lapse from the ideal of high thinking to high living is, it must be feared, more frequent in clubs made up of prosperous qualified men than in those whose members are *in statu pupillari*.

Medical Societies.

By those who do not attend medical societies, and may perhaps regard this devotion as a youthful indiscretion, the reason confessed for their abstinence is sometimes, not indolence, but a delicate disdain for self-advertisement. Modesty is indeed an admirable virtue, particularly in our rivals; but the English are somewhat prone to an excess of this fine trait, and men too diffident or hypercritical of their own work, or too much impressed by the verse expressing a desire that "mine adversary had written a book," may delay publication of their observations indefinitely so that they remain mute and inglorious, and thus may perhaps delay the progress of knowledge. The wisely modest man remains a student all his life, and recognizes a medical society as a means of easily obtaining post-graduate instruction. With the passing years the habit of attending meetings wanes, and eventually is given up altogether, ostensibly on account of the increasing calls and fatigues of professional life; as a result the individual necessarily loses touch with what is going on. He may excuse himself by saying that he can read it just as well and more quickly; but, even if he remembers to do so, the effect of the written word is not always the same as that of the spoken address. Further—and this is not very rare—laziness when disguised under the cloak of modesty may exert an unwholesome influence; a cynical attitude to societies in a senior tends to counteract the benefits that may be obtained from the give and take of debate; it may discourage others from speaking and sharing in the stimulating contest of wits which by a flash may create new ideas and strike out hypotheses worthy at least of being tested.

That those prominent and keen at societies possess the faculties which make for professional eminence and success is well shown by the records of the Royal Medical Society run by the students at Edinburgh, the presidents of which so often reach the seats of the mighty, both in the Northern Athens and in the capital of what the Scots have modestly called the southern peninsula of their country; Richard Bright, for example, was president of the Royal Medical Society before he left Edinburgh in 1813 for Cambridge, where he spent two terms before returning to Guy's. Another instance of early activity at societies as an omen of future success was seen in London about fifty years ago, when no medical meeting was said to be missed by "the three G.'s"—Sir James Goodhart, Sir William Gowers, and Professor W. S. Greenfield of Edinburgh, who reached the highest places in general medicine, neurology, and pathology respectively.

Advantages of Medical Clubs and Societies.

Medical clubs of an educational character have become much more numerous of late years, and this is no doubt associated with the legitimate rise of specialism. It is difficult to exaggerate the value of such clubs in multiplying enthusiasms and thus stimulating research work, in bringing men together, in originating and maintaining friendly relations, and so obviating the risks of misunderstandings and minimizing jealousies among men who are rivals in climbing the ladder of scientific and professional success. As the personal characteristics of the members must influence the success of such clubs and the elections, it might be urged that there is a risk of thus fostering a spirit of cliquishness; but even if this be admitted the undoubted good that results greatly outweighs any occasional harm, and for the able if prickly individual the larger societies and the journals offer ample opportunity of letting his light shine before his fellows.

A valuable and instructive, though often evaded, function of a medical club is the obligation on each member in turn to contribute a paper or demonstration; for not only is this the most excellent way of obtaining a knowledge of the subject selected, but it provides a training in the art of accurate argument and exact expression. The power of writing well is not easily acquired, much less is it an innate gift, as the autobiographical confessions of Robert Louis Stevenson and T. H. Huxley, both masters of different styles, should convince any sceptic; it demands much patient practice, and of a more exacting character than that necessary to acquire facility in public speaking, and yet this is often unrecognized by those who have not tried to set out their thoughts on paper and had the privilege of hearing the candid opinions of their readers. It is interesting in passing to compare medical writers and speakers; the successful writers have more often been physicians, as the Guy's traditions prove, whereas real oratory, a rare accomplishment, seems specially related to surgical eminence, as is so remarkably shown by the succession of William Lawrence, James Paget, William Savory, and Henry Butlin at St. Bartholomew's Hospital, and by other Presidents of the Royal College of Surgeons of England. The training in writing papers is an invaluable preparation for the production of professional reports, articles, and books, and there is, therefore, this further justification, if it were needed, for the not very popular requirement of theses for degrees in medicine at the universities. Another advantage reaped by the author of a paper is the free criticism and opportunity of reply that may follow its delivery before a club unrestrained by the presence of high authority or by the fear of the pre-

mature and comprising publicity which attends speaking at a large medical society. It is therefore important that the members of students' medical clubs and societies should be responsible for reading the papers and opening the discussions, and that their seniors and teachers, who must be treated with at least outward respect, should only exceptionally be in the chair, read papers, or be listeners. Otherwise the opportunities of education in the art of speaking in public are diminished. In 1801 Sir Astley Cooper wrote to his assistant, J. C. Saunders, "I have wished to see you join in the debates of the Guy's Medical Society. The capability of expressing our ideas in public is a source of more power than anything with which I am acquainted. It is the road to bring a public teacher to character and to fortune."[1] Lastly, let us not overlook our debt to the early medical societies for setting an example by their publications and thus leading to the appearance of medical journals.

FACULTY OF MEDICINE, UNIVERSITY OF BIRMINGHAM.

ADDRESS BY SIR FARQUHAR BUZZARD.

AT the opening of the session of the Faculty of Medicine, University of Birmingham, on October 1st, Sir E. Farquhar Buzzard, Regius Professor of Medicine at the University of Oxford, presented prizes to successful students, and gave an address entitled "Arrogance and ignorance in medicine." The present reputation of the medical profession among the general public, said Sir Farquhar, was not at all satisfactory. It was blamed almost in one breath for its medical conservatism, its surgical radicalism, and its ethical trade unionism, and, generally speaking, it lived in an atmosphere which might be described as unsympathetic and suspicious, if not actually antagonistic. The charges laid against the profession might be divided roughly into two groups—those of arrogance and those of ignorance. The terms of the former indictment included the suggestions that medical practitioners were inclined to treat their patients as fools, to assume an air of infallibility, and to display intolerance of the views of others. These suggestions, he said, contained some measure of truth. The medical practitioner, flung into practice, found himself in a world where he was called upon to discuss medical matters with patients not only lacking in scientific knowledge, but often incapable of clear thinking. None the less, if he were wise he would train himself to answer with truth and nothing but the truth, even if he did not always feel justified in imparting the whole truth. Although medicine was year by year becoming more scientific, no medical man could afford to neglect the arts of questioning and listening, and the doctor might readily earn a reputation for arrogance if he could not conduct his cross-examination with tact and indulgence. Passing to the charge of ignorance, he said that the public measured medical knowledge by the ability of doctors to cure; thus the profession was criticized because it could cure neither cancer nor the common cold. The claims for prevention of disease, however, were becoming daily more firmly established, and the future of medicine surely lay in that direction. The common cold was probably preventable, but no Minister of Health was ever likely to stand out against the outcry that would arise if he attempted to impose the appropriate preventive measures. The claim to cure disease might well be left to the quacks and charlatans; it should be the object of the profession to make its methods of practice and claims so different from those of quacks that the public should have no difficulty in making the proper distinction. In so far as the profession failed to do these things it must plead guilty to a charge of ignorance. Doctors had applied each new cure-all in turn to the treatment of every known ailment, their only defence being based on the statement that patients insisted on having the newest things in the way of cures; this was a poor defence and unworthy of the profession whose scientific status they were anxious to raise. If he were permitted to coin a motto appropriate alike to consulting room and surgery, it would be: "Give, and do, more than is required of you."

LONDON SCHOOL OF MEDICINE FOR WOMEN.

ADDRESS BY DR. JANE WALKER.

THE new session of the London (Royal Free Hospital) School of Medicine for Women was opened on October 1st, when the prizes were presented and an address delivered by Dr. Jane Walker. The dean, Lady BARRETT, welcomed sixty-five new students to the school this year—the highest entry, she said, that the school had ever known, except in the war years. It was not possible to keep pace with the demands for medical women which were made upon the school and the hospital. There were far more demands for medical women to occupy posts than there were women to occupy them. Within the past few weeks three hospitals so ardently desired a student from the school that they had begged the school itself to nominate a woman for the posts they had to offer. In recounting some of the successes of the staff and students she mentioned that Miss Mildred Warde, F.R.C.S., assistant surgeon for diseases of the ear, nose, and throat at the Royal Free Hospital, wishing also to have the M.S. of the University of London, had come out at the top of the list, with the gold medal of the University.

Dr. JANE WALKER took as the title of her address "The return of women to medicine." Many people had the idea, she said, that the entrance of women into medicine was of comparatively recent date—that is to say, belonging to the last sixty or seventy years. But, in fact, the practice of medicine by women was as old as the hills. From the beginning of time women had been quietly and efficiently tending the sick and binding up wounds. Many women doctors were in practice in ancient Greece and Rome. She thought there was some evidence that the book of Ecclesiastes was written by a woman doctor, perhaps a little disillusioned by general practice. Again, in the Middle Ages, when learning was not widely diffused, medicine was not regarded as a gentleman's accomplishment, and to a certain degree it was left to women. Ladies of mediaeval households were both nurses and doctors. In the famous school of Salerno women as well as men taught and practised medicine and surgery; at least she held the view that Trotula was a woman, and rejected the view of some German higher critics that this was the name of a book or of a body of teaching. In Spain and North Africa many a marble slab had been found commemorating a woman doctor. In Egypt women doctors must have practised for thousands of years. In our own country Sir Thomas More, in the Tudor period, earnestly wished that his daughter might spend the rest of her time studying physick and reading the Scripture. In the time of John Evelyn some women doctors, apparently, had a fashionable reputation. Probably the only act of justice that Napoleon Bonaparte ever did to any woman was to appoint a woman a professor of obstetrics. As medicine became a science and less of a mystic and empirical art, men of science declared that women were incapable of learning it, but gave them no chance of proving whether they were incapable or no.

The passing of the Medical Act, 1858, in Great Britain, although a great advance in many ways, made it impossible for women to practise medicine unless and until a university or corporate body with power to examine them would do so and grant them degrees. Looking backwards, it was almost impossible to believe that many things which were now a mere matter of course should in the past have been refused to women merely because they were women. Dr. Walker then recounted the struggle led by the three pioneers—Elizabeth Blackwell, Elizabeth Garrett Anderson, and Sophia Jex-Blake. Of these three pioneers, Sophia Jex-Blake was the most forceful and compelling personality. "You either disliked her intensely, or you were prepared to go with her to prison and to judgement." After a brief epitome of the labours of these three women, Dr. Walker mentioned some of the men who had helped in the early struggles. Some men doctors had always been in favour of women's emancipation in this respect. In the very early days nearly two hundred signed a petition in favour of women entering medicine. Among the signatories was Sir James Paget, although he did not quite approve of women in the profession. Among stalwart friends of the

women's movement were many former members of the staff of the Royal Free Hospital.

Dr. Jane Walker concluded her address with a few words of counsel to the young women students before her. She impressed upon them not only the necessity of acquiring technical knowledge and skill, but of the exercise of infinite patience, forbearance, tact, and courage, the possession of business ability, energy, and good health, and the observance of absolute loyalty to their colleagues.

ST. GEORGE'S HOSPITAL.

ADDRESS BY Dr. E. I. SPRIGGS.

At the opening of the session at St. George's Hospital, on October 1st, Dr. Edmund I. Spriggs presented the prizes and delivered an address entitled "Doctor and patient."

Dr. Spriggs described the relation between doctor and patient, beginning with the history and going on to the *etiology, method of examination, pathology, complications,* prognosis, and treatment. He remarked that his observations were founded upon thirty-three years of mistakes. The written history, perhaps, began with the account of the rescue of a surgeon by his patient, when Machaon, son of Aesculapius, was withdrawn, being wounded, from the fight, by Nestor—"for a leech is worth many other men, to cut out arrows and spread soothing medicaments." The students now entering the wards were the recruits of a great army of men who had served the physician's art; they were more fortunate than their forerunners in many respects, especially that of intellectual freedom; moreover, the means of controlling and arresting disease were fuller than ever before. Doctors used to wear some sort of impressive costume, and de la Fouchardière suggested that only a very complacent person would let himself be cured by a doctor in a tweed *suit who did not even* any longer speak Latin. This little matter was, however, adjusting itself in the whirligig of time, for a modern costume had appeared—the white coat of work; the wish was doubtless present, as it was put on, that wisdom and skill could also be woven at so much a yard.

In the course of the address the speaker said: "If the patient comes to you because you are known to be competent, well and good. But if you are chosen because your patient's dinner or dancing partner told her that you were *absolutely the* only man, or whatever it is—beware. It is a danger to have emotional persons going about saying Dr. So-and-so is wonderful; as soon as many people say the same it becomes *le dernier cri, and this lives only* a little longer than a mayfly. Nearly every patient will be a single-minded person, seeking relief and ready to give you all possible help in your work. But you will learn to recognize a few folk who are less anxious to keep to the truth than to produce a certain impression; you will also become familiar with the sublime unconscious selfishness of the neurotic, and with the 'imitation great,' who show their importance by giving trouble. On the part of the doctor the relation to the patient would be a wrong one if there were any trace of insincerity. The difference between you and the charlatan is that you are there to do the patient good by any method, and the charlatan is out to sell his wares, whatever they may be. You will judge yourself severely and others not at all. Humbugs of one kind or another are with us; it has never been otherwise. They come as regularly as waves on the beach; every ninth one is perhaps a bit bigger, but, like waves, they go."

The students were advised by Dr. Spriggs to avoid using long words when shorter ones would do; they were recommended always to listen carefully *to the patient*, even to the neurasthenic, and to be particularly cautious with a person who related all the mistakes which other doctors had made, remembering that he might, in due course, add his *present doctor to the collection*. They were advised strongly to get into touch with other doctors who had seen the patient. The family doctor was the unit of medical work, and additional opinions were most useful if they were connected with the information which he could supply. Instances were given of patients who had gone from doctor to doctor without any one control, with disaster to themselves. It was *important to learn* to examine the patient upon a definite plan, and to avoid the pitfall of making a diagnosis upon one finding, which may not be the cause of the illness.

Dr. Spriggs continued: "It is essential not to allow anxiety to bias judgement. If there is one place more than another where a fidgety mind is not wanted it is in the sick-room, and the doctor who worries too much takes away from his own usefulness; though I suspect that he who does not worry at all is no doctor. Doubt and anxiety *will be lessened* if you are able so to arrange your work that you deal with a problem at the time. Keep good reference books, and read up the case at once. To-morrow fresh puzzles will come and drive the finer points of this *one out of your mind*. On the part of the patient the worst complication is mistrust. This is only natural in the first instance, and must not be resented. By the time that you have done all in your power to help your patient it will nearly always have vanished. Faith is, of course, a help. De la Fouchardière, our cynic, says that is why the clergy go to Vichy and the doctors to Lourdes. . . . How full a doctor's life may be of satisfactions and friendships you will learn for yourselves. You will not be able to get all your patients well; it would be unreasonable to expect a man who is not getting better to be as pleased and grateful as one who recovers. But he very often is, knowing that you have done all you can think of for his relief. If an exact relation between success and gratitude is expected there will be disappointment. Well! you do not work from any peddling motive, and if you have learned to laugh at yourself you will have a good deal of fun. On balance, the rewards are more than the deserts. . . . It is generally better to tell an intelligent person the truth about his illness, in as simple language as possible, avoiding technical terms and all details which may be misinterpreted. The case of cancer is *sui generis*, and to destroy hope in the mind of any patient is inexcusable; it is also unwise, because you do not always know. We are not there to pass sentence. Remember *'Guérir quelquefois, soulager souvent, consoler toujours.'*

"In all these matters," Dr. Spriggs concluded, "you will have the advantage of learning your profession in a country in which the standard and the conduct of practice is higher than in any other; in a city the streets of which were trodden by Harvey and Sydenham, Hunter, Jenner, Young, and Lister; and at a hospital which has had more than its share of these pioneers of medicine. The physicians and surgeons at St. George's have played a part in other spheres besides medicine—in science, literature, art, and sport. That is one reason why they have trained so many good doctors, and you will, if you are wise, carry on our hospital tradition. Don't have *all your friends doctors. Be a man among men* away from the sick-room. I had the idea as a student that all the main discoveries in medicine had been made, and that new ones would come only from the exceptionally able, and after laborious and abstruse research. Gentlemen, it was not so, and it is not so now. 'The sphere of our knowledge expands without ceasing, but as it increases so do the number of its relations with the unknown.'"

WESTMINSTER HOSPITAL.

ADDRESS BY Dr. F. N. KAY MENZIES.

At Westminster Hospital the inaugural address was given, on October 1st, by Mr. F. N. Kay Menzies, medical officer of health and school medical officer to the London County Council. His theme was the application to London of the Local Government Act, 1929.

Dr. Menzies explained that this Act transferred to the London County Council as from April next the whole of the services of the Poor Law guardians and the powers and duties of the Metropolitan Asylums Board. This meant, in effect, the transference to one public authority of over one hundred hospitals and other institutions for the treatment of the sick. With the beds it already provided for mental cases and for various other purposes the council would presently have under its direction and *control no* fewer than 75,000 beds for dealing with every variety of disease, or five times as many beds as the total

for the voluntary hospitals of London. Dr. Menzies briefly reviewed the history of the past century in order to show what had led up to this revolution—the rapid industrialization and growth of town life, which had created many new health problems, the emergence, by the end of the nineteenth century, of a "sanitary conscience," and, later, during the last twenty-five years, the entrance of public authorities into the domain of treatment as contrasted with prevention. The evolution of public health administration had followed a logical sequence: first, communal health or environmental hygiene, as exemplified by housing or water supply, and then personal or individual health, as exemplified by services dealing with tuberculosis and venereal disease.

Dr. Menzies next turned to the Poor Law, and pointed out that if a sick person could not obtain medical attention elsewhere the Poor Law guardians were required to provide it—they had no choice in the matter. That was the great distinction between the Poor Law hospitals and the voluntary hospitals; the latter carried no legal obligation, and made their own selection of cases. It was important to remember that the great bulk of hospital treatment in this country was provided by the Poor Law guardians out of the rates or by public authorities out of the rates and taxes. These services were represented in England and Wales by 350,000 beds, as compared with 50,000 in voluntary hospitals. Therefore the London County Council was not creating an entirely new public service; it was simply taking over and centralizing under one authority what was actually a going concern. The agitation in favour of transferring the duties of guardians with regard to the treatment of the sick to the public health authorities, and thus preventing any stigma upon the recipient, had been going on for twenty-five years, and Parliament had continually preferred the public health authority, as distinct from the Poor Law authority, for providing the new health services.

It was difficult to say how this new public hospital organization would affect the voluntary hospitals. But the wisest course was for both the public authorities and the voluntary hospitals to realize that this was an unmistakable case for co-operation or voluntary partnership in the interests of the sick. The worst thing that could happen would be antagonism, which could have only one result—namely, that the public purse would prevail. The policy of the London County Council had always been one of cordial co-operation with the voluntary hospitals, whose assistance it had sought. In London, at all events, there should be no ground for apprehension. The council and its medical staff would shortly be called upon to undertake the greatest responsibility that any public authority had ever been asked to shoulder, and the speaker begged for the cordial sympathy and wholehearted support of all genuinely interested in the care of the sick.

Annual Dinner.

The past and present students of Westminster Hospital met at dinner at Grosvenor House, Park Lane, on October 1st, to the number of 120, under the chairmanship of Mr. Stanley Dodd. The toast of "The School" was proposed by its chairman, Mr. A. E. W. Marshall, and the dean, Dr. A. S. Woodwark, in responding, reminded the gathering that this was the commencement of the ninety-sixth year of the medical school and the two hundred and tenth of the hospital. Last year, he said, a record was reached in the number of students entering, and this year the number had been maintained. The school had an excellent athletic as well as an educational record. The great event of the year had been the opening of the sports pavilion, the gift of the visiting medical staff to the students, at a cost of £1,100. It had been for long a reproach to Westminster that it did not possess a school ground worthy of the name; that reproach had now been wiped out by the provision of a school ground second to none, within half an hour's journey of the school. Dr. Woodwark also referred to the post-graduate classes; these had been attended by thirty-seven general practitioners, and over thirty surgeons from all parts of the country came up for a radium course given by the staff of the hospital during July of this year; this was the first radium course ever given by a hospital. The dean spoke of the steady progress of the school during the last ten years, and of his hopes for the next decade.

Mr. Stanley Dodd proposed the health of the "Past and Present Students," and entered upon some reminiscences of former athletic achievement. One of his pieces of advice to students, which was heartily applauded, was not to work too hard—to perform their tasks conscientiously, but to have adequate intervals for play. The toast was responded to by an old student, Dr. F. F. Bond, and by a present student, Mr. A. S. V. Daniel, secretary of the students' club, who expressed the thanks of the students for the provision of athletic facilities. Sir James Purves-Stewart, in a happy speech, toasted "The Guests," among whom he mentioned Dr. F. N. Kay Menzies, the orator of the afternoon, Dr. Florence Barrie Lambert, chairman of the Health Committee of the London County Council, and Mr. Kenneth Wolfe-Barry, chairman of the House Committee, who bore a name linked with Westminster for the last half-century. Dr. Kay Menzies responded with some entertaining reminiscences of his student days in Edinburgh, and a very enjoyable evening concluded with the toast of "The Chairman," proposed by Mr. Rock Carling.

ST. BARTHOLOMEW'S HOSPITAL.

OLD STUDENTS' DINNER.

The new winter session at St. Bartholomew's Hospital opened with the customary old students' dinner; this was held on October 1st in the Great Hall of the hospital, with Sir Frederick Andrewes in the chair. He was supported by Lord Stanmore, treasurer of the hospital, and other members of the lay staff; Sir John Rose Bradford, P.R.C.P.; Sir Holburt Waring; Sir Humphry Rolleston; Air Vice-Marshal Munro; the Masters of the Salters', Haberdashers', Drapers', Ironmongers', Vintners', and Apothecaries' Companies; Sir William Lawrence; the architect of the new extensions of the hospital; and senior members of the honorary medical staff.

After the Royal toast had been honoured, the chairman explained that, as usual, formality would be absent; he proposed, however, to recount something of the history of the hospital during the preceding twelve months. The hand of death had removed Sir William Church, for so long the chairman at such dinners, Sir Dyce Duckworth, Mr. A. E. Cumberbatch, Sir Anthony Bowlby, and Sir Charles Harding. Those present were invited to admire the ceiling, completely cleaned for the first time in 150 years, and brilliant in the light of the new system of illumination. Many of the pictures were no longer to be seen on the walls; in ordinary circumstances they would be found on easels in the middle of the hall, where they could be examined to better advantage than formerly. The floor of newly polished oak was also to be admired. Outstanding among the changes at the hospital must be accounted the new surgical block, which was approaching completion. The internal arrangements were exceptionally good, and every effort was being made to promote surgical efficiency. Each surgeon would be provided with a self-contained floor comprising two wards, an operating theatre, and a private room. For administering anaesthetics gas and oxygen were being "laid on" to each theatre from the basement, and Sir Frederick, in imagination, foretold the time when this innovation might be extended still further, and the anaesthetist be able to play upon a keyboard, supplying anaesthetic fugues to meet all requirements in all theatres at once. The work already in progress had cost more than £200,000, of which rather less than half had already been provided. The extensions undertaken so far had included a new block for out-patients, a pathological block, and a new nurses' home to accommodate 260 out of the 400 sisters, nurses, and probationers. Further additions contemplated included the extension of the medical school by the provision of new buildings on a site which had been already acquired, the erection of a residential college, and the establishment of an institute for research. Sir Frederick Andrewes remarked that it was an open secret that an appeal for funds would soon be launched, and he expressed the hope that Bart's men would give their hearty support by commending it wherever financial assistance might be derived for this most deserving cause. He commented on the

coincidence that there hung on the wall of the Great Hall a board commemorating the names of those who had subscribed to the rebuilding of the hospital in 1729; he ventured the belief that the bicentenary of this event fell appropriately at the time of the present reconstruction, and would serve as a stimulus to many to serve the poor of their generation as generously as their predecessors. Lord STANMORE proposed the health of Sir Frederick Andrewes, which was drunk with musical honours. The large assembly of old students then adjourned to the library for social converse on an even less formal basis.

MIDDLESEX HOSPITAL.

ADDRESS BY DR. E. A. COCKAYNE.

AT the opening of the ninety-fifth winter session of the Middlesex Hospital Medical School on October 1st, the prizes gained during the past year were presented by Mr. SAMUEL COURTAULD, and Dr. E. A. COCKAYNE delivered the inaugural address, entitling his subject "Life's endless chain."

Dr. Cockayne said that heredity was a branch of medicine that was almost completely ignored in textbooks and by teachers in medical schools, yet clinical observation was daily adding to the great store of knowledge already amassed on this important subject. Even now, he said, we could foretell of many human characters whether they were transmissible or not, and in what proportion of the offspring they might be expected to appear. None the less, the science of eugenics was in its infancy, and the application of Mendelian principles to the human race would for many years remain limited; moreover, he did not see how they could be applied to man as effectively as to the lower animals, the methods employed in stock-breeding not being available for human beings. The stamping out of undesirable characters would be easy if they were dominants, but it would be a long and perhaps impossible process if they were recessives. Even if the inherited afflictions of the human race were eliminated, they might still arise again as fresh mutations. But for the patient work of the microscopists, the long and difficult experiments in breeding carried out by botanists and zoologists, and the labour of the chemists, little would be known to-day about heredity in man. The nature of many inherited defects was still obscure and awaited investigation. That branch of medicine alone, said Dr. Cockayne, was sufficient justification for giving students a thorough grounding in the basic sciences of chemistry, physics, botany, and zoology.

Dr. T. IZOD BENNETT, dean of the Medical School, stated that, in the Bland-Sutton Institute of Pathology, Professor James McIntosh with his assistants was pursuing researches into the nature of the filterable viruses; cancer research was carried out in various forms in nearly every laboratory of the institute, and through the help of the British Empire Cancer Campaign a systematic inquiry was being conducted into the nature of certain groups of malignant tumours. Valuable work was being done in the Courtauld Institute of Biochemistry, including an investigation of glandular extracts of medical utility, which was being conducted in collaboration with certain important firms interested in pharmacological products of this class.

ANNUAL DINNER.

The annual dinner of past and present students of the Middlesex Hospital Medical School was held the same evening at the Savoy Hotel, with Mr. A. E. WEBB-JOHNSON in the chair. In proposing the toast of "The Middlesex Hospital and Medical School," Mr. Webb-Johnson gave a summary of the progress that had been made in rebuilding the hospital. Gigantic as the task was, he said, it was now within measurable distance of accomplishment, and within a few weeks they would taste the first fruits of their labours. The board had decided that two wards in the new surgical wing should bear the names of old surgeons of the hospital—namely, of Sir Charles Bell and Sir John Bland-Sutton. The new wing was no Tower of Babel; it had been built to last, and its builders had used a common language which assured them of the Divine blessing. About £300,000 given quickly would secure the completion of their task; those with a taste for really sound safe investment could do no better than put their money into the Middlesex Hospital; it would be returned to them one hundredfold, not in cash, but in the relief of suffering and the prevention and cure of disease. The gift of £300,000 for the erection of a new nurses' home was perhaps the greatest ever given to any hospital in this country by an individual donor during his lifetime, and so touched was the Queen by this gift that she had made her first public appearance after the King's illness in order to lay the foundation stone. Turning to the work of the scientific departments of the hospital and medical school, Mr. Webb-Johnson said they were proud to remember that during the King's illness scientific investigations had been carried out by Middlesex men at the Middlesex laboratories. The epic fight for the King's life recalled to his mind a tribute that had once been paid to the voluntary hospitals by Sir Frederick Treves, who, speaking to King Edward after his severe illness, said, "Sir, you have had as much care and skill in your illness as the humblest of your subjects." Prince ARTHUR OF CONNAUGHT, chairman of the hospital, in responding, said that the hospital had passed through an extremely difficult time, but now the dawn was breaking and there was every reason for feeling optimistic about the future. Dr. IZOD BENNETT, in referring to his recent appointment as dean of the Medical School, said that he was supported by the knowledge that four ex-deans were present that evening. He himself could claim no credit for the progress that had been outlined by previous speakers, but he had studied the methods by which his predecessors had achieved so much. The qualities of a dean, he said, were tact modified by firmness, and skill in making a timely compromise when necessary. The Medical School was fortunate in having acquired as its treasurer a urological surgeon, for it was common knowledge that men of this class concealed beneath a steely exterior a spirit of exuberant romanticism. Mr. ERIC PEARCE GOULD, in giving the toast of "The Guests," welcomed the presence of Mr. Lints Smith, manager of the *Times*, and paid tribute to the late Mr. Bernhard Baron, two members of whose family were present as guests. They were also under a debt of gratitude to Mr. J. B. Joel for large donations to the hospital and the endowment of a professorial chair to the school. Another guest, Lord Lee of Fareham, he said, was giving devoted service to the Radium Commission, and was to be congratulated on his good fortune in having two teachers of the Middlesex Hospital Medical School to guide him in his work. Lord LEE OF FAREHAM, in responding, said that a good case could be made out for appointing a layman as chairman over a committee of experts; the experts would never agree among themselves, but would always find themselves in accord with a layman, who could not possibly be a professional rival. Major-General HAROLD B. FAWCUS, D.G., Army Medical Services, also responded on behalf of the guests, and Sir ARNOLD LAWSON proposed the toast of "The Chairman." At the conclusion of the dinner students, past students, and their guests adjourned to a reception room for conversation and the renewal of old associations.

ROYAL MEDICAL BENEVOLENT FUND.

AT the two recent meetings of the committee £855 was voted in grants to sixty-four applicants, and £537 was voted in annuities to twenty beneficiaries over 60 years of age. The following were some of the cases helped.

L.R.C.P., M.R.C.S., aged 79, who, owing to deafness and age, is unable to follow his profession. His wife's savings have been exhausted by the claims made upon him by his family, and his only income is £52 a year, contributed by two nephews. Voted annuity of £70.

L.R.C.P. and S., aged 79, whose savings have all been exhausted. She is the inmate of a home, where she has to pay rent of £19 10s. Her only income is the old age pension of £26. Voted annuity of £36.

Widow of M.B., aged 68, whose only income is £52 a year from a daughter who earns 30s. a week. Voted annuity of £26.

Widow of L.R.C.P., M.R.C.S., aged 74, unable to work and has only the old age pension. Voted annuity of £26.

Daughter of M.R.C.S., aged 69. Has an income from investments of £34 a year. Voted an annuity of £26.

Subscriptions and donations are urgently needed, and should be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

Scotland.

Scottish Health Services.

A circular issued by the Department of Health for Scotland to local authorities instructing them in their duties and responsibilities under the Local Government Act of this year indicates in broad outline the revolution in the Scottish local government system of health services brought about by that Act. The area of administration of the major public health services will be the county or large burgh, and a new public health local authority is created in the counties for those health services. The authority responsible for health services becomes identical with the authority responsible for medical services under the Poor Law, and also with the authority responsible for school health administration. Power is given to provide assistance which might be given by way of poor relief or by virtue of another enactment exclusively under such other enactment. Assistance includes the maintenance and treatment of sick persons, and provision ordinarily made under schemes of maternity service and child welfare or school health administration. Power is also given to local authorities to reorganize the hospital facilities at their disposal, and to provide hospital accommodation for the sick of all classes. The percentage grants for public health services are abolished and a block grant is substituted. It is a condition of the payment of the block grant that adequate public health services are provided. An authority is not required to appoint a public health committee, but has power to do so, and it may also appoint a public assistance committee, or alternatively may appoint a single committee for public health and public assistance with subcommittees for these purposes. The relationship between these two services becomes much closer under the Act, and in the circular emphasis is laid on the fact that it becomes possible, as it is indeed desirable, for a large number of sick persons who apply for assistance to receive that assistance under the public health service. The relation between the public health committee and the education committee will be gradually developed in the light of experience, and meantime authorities are counselled that the school medical service should be definitely linked up with the other health services, and in particular with the maternity service and child welfare schemes. Under one authority these services may now be all co-ordinated, and if there is to be any division of responsibility in respect of the children it should be at the age of 1, till when the care of the mother and of the child are naturally grouped together. From that age till the end of the school period the welfare of the child should be regarded as a single service.

Organization of Staffs.

In the matter of the organization of staffs the department takes the view that the whole medical, veterinary, and sanitary staff should be under the general direction and control of a chief medical officer. It also takes the view that ordinarily it will be best, at least in the less populous areas, that the assistant medical officers should so far as possible carry out all public health duties within a particular district rather than confine themselves to the carrying out of a particular branch of public health work throughout the whole area. At the same time each medical officer should as far as possible be equipped with special knowledge of one branch of the health service. This form of organization where feasible will not only avoid unnecessary travelling, but will, in the view of the department, be in the best interests of the officer concerned. Where a considerable number of medical officers are employed the chief medical officer should have under him a grade of chief assistants acting as heads of the various departments. Vacancies in the medical officership of small burghs occurring after May 15th, 1930, must be filled by the appointment of the county medical officer, so that in course of time the only medical officers of health in the country will be those of the county councils and the large burghs. Local authorities are advised to consider how far it is possible for them to utilize the services both of the consultants and of the general medical practitioners of the area in the clinical duties under the several health schemes.

Development of Hospital Services.

The provision of assistance which might be given, either by way of poor relief or by virtue of other enactments—now commonly spoken of as "the break-up of the Poor Law"—is left for detailed consideration in a later circular. Its importance is emphasized, however, in relation to the provision of hospital facilities, and the department has no doubt that local authorities will desire so soon as practicable to make hospital treatment a matter of public health and not of poor relief. Dealing with hospital provision, the circular recalls and endorses the findings of the Mackenzie Committee in 1925 as to the shortage of hospital beds in Scotland, and expresses the view that the shortage is no less now than it was when the committee reported. The ultimate object of any hospital policy must be to bring a complete and efficient hospital service within the reach of all. The Mackenzie Committee considered that this end could best be obtained by the full development of both voluntary and public authority services working in co-operation. With this view the department is in full agreement, and it regards it as of the first importance that the development of hospital services in every area should be a matter of agreement between the public authorities and the voluntary hospitals. Hitherto the duties of local authorities in the provision of hospital beds under various schemes have in many cases been discharged through the agency of voluntary hospitals, and in the less populous areas this method may continue to be the most effective way of meeting the need for additional accommodation. In other areas it may be found expedient that the local authority itself should provide the accommodation, but "whatever course is followed the essential point is that there should be an agreed policy between the local authorities and the managers of the voluntary hospitals." The machinery for securing contact between the public authorities and the managers of voluntary hospitals has been provided by the setting up of regional committees. Before approving schemes for the utilization of existing institutions or for the extension of facilities, the department is required to consider the whole accommodation, voluntary and other, for the area, and to satisfy itself that the local authority has taken reasonable steps to seek and continue to secure full co-operation with the hospitals and university or medical school within or serving the area. The most effective use of all the institutions that will now pass into the hands of the new authority is fully discussed; it is concluded that most of these can be usefully devoted to other purposes than hospitals, and the ideal of providing hospital units large enough to combine elasticity of accommodation with economy and efficiency of administration is enunciated as the ultimate aim to be kept in view. It is suggested that pressure on in-patient accommodation may be considerably relieved by the provision of out-patient and diagnostic clinics in connexion with hospitals, and that the service of those clinics might be made available to the medical practitioners of the area.

Effects of the Block Grant.

On the debatable question of the recovery of costs of treatment, the department points out that it is lawful, but not compulsory, for the local authority to recover costs, and expresses the view that recovery should not be enforced to an extent that will discourage persons in need of treatment from obtaining it. Authorities are reminded of the condition of the block grant—namely, the achieving or maintaining a reasonable standard of efficiency and progress in the discharge of their functions relating to public health services—and indication is given that a higher standard will be required than has sometimes been attained in the past. "The amount of relief given by the new grant system is in a number of areas so material as to create a new set of circumstances, and the authority should review the adequacy of its services in the light of its new financial resources."

The whole tenor of the circular clearly shows that a new era of development of health services is opening in Scotland. In that development the medical profession is vitally interested, and it will be the duty of the Divisions of the British Medical Association and of the regional professional committees to keep a watchful eye upon the

progress of events and to proffer, at the appropriate time and place, helpful criticism and counsel.

Other circulars to be issued by the department will deal with (*a*) infectious diseases (including tuberculosis and venereal diseases); (*b*) milk supply, unsound food, and food and drugs; (*c*) maternity service and child welfare; (*d*) school health administration. It is announced that copies of these circulars may be obtained, price 1d. (post free 1½d.), from H.M. Stationery Office, 120, George Street, Edinburgh.

Promotion of Public Health in Scotland.

The fifty-fifth annual conference of the Royal Sanitary Association of Scotland, held at Kirkcaldy on September 10th, 11th, and 12th, was attended by some 500 delegates. The president, Mr. W. J. Harvey, Edinburgh city treasurer, in his address on economics and public health, said that at its lowest estimate public health activity by local authorities or by the State could be justified only in so far as it made a material contribution to the production of wealth; it could contribute to that end only by emphasizing prevention as against cure. Accordingly, he pleaded for the educative influence of the public health administrator being brought to bear upon the mass of the population, with a view to each citizen realizing his responsibilities to the State in respect of the maintenance of his own health. The public health service of the country would never be satisfactory until the individual was made to feel that he was part of the machine. As a result of enlightened propaganda, Treasurer Harvey looked forward to a diminution in the demand for treatment facilities. In a popular evening lecture Dr. J. Parlane Kinloch, chief medical officer, Department of Health for Scotland, defined the meaning of an adequate health service. He traced the growth of the modern health movement, and stressed the desirability of taking a wide view of the problem. Dr. Kinloch then explained the reasons for the introduction of the new Local Government (Scotland) Act, and outlined its scope, with special reference to the health services. Dr. John Guy, deputy medical officer of health, Edinburgh, read a paper entitled "The dietary of the people." He said it might be taken as an axiom that a well-fed animal was a disease-resisting animal, and a well-fed man, although housed in an inferior dwelling, would resist disease better than a poorly fed one in a better house. Nutrition was the basis of well-being. After a reference to the constituents of food, the relative amounts required and especially the quality, Dr. Guy dealt exhaustively with the financial aspect. Working on a purely theoretical basis, and giving adequate amounts of all the constituents of a diet, he found that a fully balanced and varied ration could be provided for 6s. a week, but this required some knowledge of food values. Recently he had made a detailed study of the dietaries of thirty Edinburgh families, and had concluded that, if these families were to be regarded as typical of the bulk of the population, vast numbers of persons in this country were living on diets which were only slightly over the bare subsistence allowance. He felt that there was great need for the education of the people in the buying and the preparation of food. Councillor W. Brownhill Smith (Glasgow), in a paper on the smoke nuisance, said that to-day smoke from all sources whatever could be prevented. The hope of the future lay in the extended use of electricity, and he hoped that the electrification of the railways in Scotland was a reform which would not be too long delayed. The president-elect of the association is Dr. T. F. Dewar, Department of Health for Scotland.

Glasgow Dental Hospital.

The initial step was taken in the erection of a new and up-to-date dental hospital in Glasgow on September 23rd, when Lord Provost Sir David Mason cut the first sod on the site at 201, Renfrew Street. Sir John Stirling Maxwell, Bt., who presided, said that the present hospital was quite inadequate to meet the increasing demands of the city and district for dental treatment. Whereas in 1921 the number of patients was 24,000, in 1928 there were no fewer than 74,000, an increase of 200 per cent. in seven years. The nation had hitherto been very careless in regard to the care of its teeth, but it was now beginning to find out its mistake, and to realize that not only comfort and appearance, but health itself, depended upon proper attention being given to the teeth. For the new building which they were about to erect they had in hand £30,000, but the large sum of £60,000 was still required to ensure its adequate equipping and endowment.

Ireland.

Housing Conditions in the Free State.

In the fourth volume of the Census of Population, 1926, which is published by the Department of Industry and Commerce, Mr. John Hooper, Director of Statistics, discusses housing in the Irish Free State. The report, which contains much valuable information, describes the housing conditions of all persons in private families, and deals with 94 per cent. of the whole population. Most of the inhabitants, it is revealed, live in three-room dwellings, this being the case with families of two persons or more up to those with a total of eleven; the family of five members is the most usual in each size of dwelling from two to nine rooms. The compilers of the report point out that in the statistics of other countries families having more than two persons to each room are considered to be overcrowded. Accepting this definition, overcrowding in the Free State in 1926 existed in the following degree: 75.2 per cent. of persons in one-room dwellings; 59.3 per cent. of those in two rooms; 36.9 per cent. of those in three rooms; and 17.2 per cent. of those in four-room dwellings. It is disclosed that 24,849 persons in the Saorstat, representing 2,761 families with nine persons in each, resided in two-room dwellings; each of these families should have had a five-room dwelling if overcrowding was to be avoided. In a table designed to show the changes that were necessary in 1926 to ensure that not a single family in the Saorstat should suffer from the overcrowding as defined, it is set out that in 1926 there were 22,915 families living in "overcrowded" conditions in one-room dwellings; 13,121 should have had two rooms, 6,665 should have had three rooms, etc., in order not to be overcrowded. There were 39,615 families living in two rooms; 22,576 should each have had three rooms, 11,844 four rooms, 4,325 five rooms, etc. There were 10,820 families each with four rooms; 8,366 of these should each have had five rooms, and the remaining 2,454 should have had six rooms. It is emphasized that along the western seaboard and in counties Dublin and Kildare the rural population are most overcrowded. In the Munster counties, except Kerry, and in counties Carlow, Kilkenny, and Wexford and Meath, the rural population are best housed; Wexford has the best housing, but in Mayo, Donegal, and Kerry the housing is much worse than in any other county. Contrasting death rates, it is found that they are much smaller in rural than in town areas. In Mayo, for instance, with 41.7 per cent. in overcrowded houses, the general standardized death rate is only 11.8 per 1,000, as compared with 15.2 in the twenty-four best-housed urban districts, with only 15.2 overcrowded. The percentages of population overcrowded in the four provinces, including town and rural areas, are: Leinster, 27.5; Munster, 22.9; Connaught, 32.8; Ulster (three counties), 29.6. The towns of the three Ulster counties had the best housing, the percentage of persons living more than two in a room being 14.6. Of the thirteen towns in county Donegal with a population of over 500, Moville and Rathmullen had less than 10 per cent. overcrowded; in four others the percentage was less than 15, in five others less than 20, and in the remaining two it was 20 and 25. Towns with over 1,500 inhabitants reported as being most overcrowded are: Dublin City, 45 per cent.; Edenderry, 38 per cent.; Limerick City, 37 per cent.; Kildare, 36 per cent.; Newbridge and Newcastle-West, 34 per cent.; Tullamore, Drogheda, and Clara, 33 per cent.; Tipperary, 32 per cent.; Ballinasloe, 31 per cent.; and Cork City, Waterford City, and Sligo, 29 per cent.

largest proportion of the population in Scotland; a three-room dwelling in Saorstat Eireann; and a four-room dwelling in Northern Ireland, Wales, and England. In Wales 41.5 per cent. of the population live in dwellings of six or more rooms, and only 0.5 per cent. in one-room dwellings. It is shown that a much larger proportion of the population live in one-room tenements in Dublin than in Glasgow, but, taking the one- and two-room dwellings together, a much larger proportion live in these small dwellings in Glasgow (64.7 per cent.) than in Dublin (50.1 per cent.). In Dublin the size of the dwelling in which the largest proportion of the population live is the one-room tenement: in Cork and Limerick two rooms, in Waterford three rooms, in other towns four rooms, and in the rural districts three rooms. The towns, other than county boroughs, have a large percentage (29.7) in dwellings with six or more rooms. In Leinster and Munster the four-room dwellings house the largest proportion of the population; in Connaught and Ulster the three-room dwellings. From 1911 to 1926, it is pointed out, there was a remarkable increase in the county boroughs in the population of persons living in less than five rooms, and a still more striking decrease in the remainder of the inhabitants. The decrease in the population living in five rooms or more is suggested to be due in the case of the provinces to the decrease in the number of Protestants, etc., and in the case of Dublin, partly to the removal of more prosperous families to the suburbs. The number of persons living in one-room tenements or dwellings decreased much faster than the general population since 1901. The numbers of persons living in one-room tenements in 1926 were: Dublin city, 78,920; other county boroughs, 11,097; rest of Saorstat, 50,044; total, 140,061. Thus more than one-half of these persons resided in Dublin city. It is shown by means of diagrams how infantile mortality increases in association with overcrowding. The lowest figure in the Dublin area was that of Clontarf and Howth; the highest, North City No. 2. The percentage of overcrowding in the first instance is 9.6; in the second 63.4. The death rate under 1 year per 1,000 births is 79 in the first, and 170 in the second. In a survey of the housing conditions as affecting different occupations, it is pointed out that painters are the worst housed of the skilled occupations. The families of tinsmiths appear to be unusually large. Railway firemen, waiters, motor mechanics, and Civic Guards have families less overcrowded than the size of the dwelling would suggest; probably they are comparatively young, and their families small. In the better-housed occupations married publicans, farmers with over 200 acres, teachers, and farmers owning 50 to 100 acres, appear to have larger families than others in about the same size of dwelling. Farmers with 50 to 100 acres have slightly smaller dwellings than clerks, but much larger families; farmers with over 200 acres have dwellings of much the same size as dentists, civil engineers, etc., but much larger families. Teachers have much the same housing as farmers with over 200 acres.

Salaries of County Mayo Medical Officers.

The Ministry for Local Government and Public Health notified the Mayo Board of Health, at its meeting on September 20th, that the salaries of the county surgeon and of the dispensary doctors had been increased by sealed order. In regard to the salary of Dr. McBride, county surgeon, the Minister for Local Government and Public Health pointed out that the claims of Dr. McBride to increased remuneration had been before the Board for a considerable time. As, however, the Board had failed to award a salary commensurate with the duties of this officer, the Minister had felt constrained to make an order determining that the salary to be paid should be £800 a year. An order was also sent fixing the salaries of the medical officers of the dispensary districts in County Mayo at the amounts shown in the schedule attached to the order. In the case of some of the medical officers with long service the scale fixed by the Minister means an immediate increase of over £100 per annum. The Mayo Health Board unanimously protested against the action of the Minister in increasing the salaries of the medical officers against its wishes.

England and Wales.

Vital Statistics for 1928.

TABLES in the *Registrar-General's Statistical Review of England and Wales for the year 1928* (Part I, Medical)[1] follow, with minor variations, the same sequence as in previous years, and embody a comprehensive analysis of the birth rates, death rates, rates of infant mortality, and of natural increase of the population; the estimate of the number and distribution of the inhabitants of England and Wales is based mainly on the census returns of 1921. The birth rate for the year 1928 was 16.7, which, with the exception of the rate for the year 1927 (16.6),[2] is the lowest yet recorded. The crude death rate was 11.7 per 1,000 of population, as against 12.3 in 1927. The corresponding standardized rates—namely, those which would have been recorded if the sex and age constitution of the population had been the same as in 1901—were 9.9 and 10.6, the figure for 1928 being lower than in any other year. Yet another record figure is that of deaths of infants under the age of 1 year: the rate during the year was 65 per 1,000 births, an improvement even on the figure for 1923, which was 69. The mortality from the epidemic diseases was far less than in the previous year, largely owing to the lower mortality from influenza, which was 196 per million living, as against 567 in the previous year. The death rate from influenza was the lowest since 1914. The mortality from diseases of the respiratory system, the lowest recorded, was 1,507 per million. On the other hand, for cancer the crude death rate figures (1,425 per million living) were higher than in any preceding year, the increase over the figure for 1927 (1,376 per million) being approximately equal for the two sexes. Since 1920, until when the figure had for some time shown a tendency to decline, the death rate from diseases of the circulatory system has, except in one year (1923), steadily risen, being for the years 1924, 1925, 1926, 1927, and 1928 respectively, 2,044, 2,160, 2,181, 2,489, and 2,669 per million living. Maternal deaths from puerperal sepsis and accidents of pregnancy and childbirth were equal to a rate of 4.42 per 1,000 live births, the highest recorded in the eighteen years for which comparable figures are available. The suicide rate showed a slight decline from 125 to 124 per million living, this lower figure being due to a diminished rate for males, that for females actually showing a slight increase. Deaths returned by His Majesty's coroners as resulting from motor accidents rose from 4,492 in 1927 to 5,251 in 1928. Excluding deaths from collisions between two different types of vehicles, the deaths caused by motor cars increased from 1,292 to 1,550, and those by motor cycles from 940 to 1,043.

Trowbridge and District Hospital.

For more than forty years the Cottage Hospital in the Halve, with its eleven beds, has served the needs of Trowbridge, but latterly its accommodation and equipment has proved inadequate, and a new building had to be obtained. So long ago as 1921 Dr. C. E. S. Flemming called attention to the difficulty of dealing satisfactorily with the sick and injured, and in May, 1924, it was determined to provide a new hospital at a cost of £16,000. Adcroft House with its grounds was acquired in 1927, and a successful appeal for funds was launched early in the following year. The house has been retained as the administrative block of the new hospital, very little structural alteration being necessary: from it there now extend new buildings of the "ground-floor" type, a continuous communication being established by a corridor from one end of the hospital to the other. On the west of the administrative block is a children's ward containing six beds; there are also three private wards for men, and a general men's ward of eight beds. On the east side are the maternity ward with six beds, two private wards for women, a main women's ward of eight beds, a night nursery, and a labour ward. On the north side of the corridor is an operating block, including an x-ray room.

[2] *British Medical Journal*, May 11th, 1929, p. 874.

A large north light window gives ample illumination during the day-time, and the electrical equipment is of the most modern kind. Wooden sun balconies painted white have been erected, with extending revolving blinds to shade the terraces. The institution stands in naturally pleasant surroundings with green lawns and flower and vegetable gardens. In the absence of Lord Radnor, who had hoped to be able to perform the opening ceremony, the Marquess of Bath took his place. The president of the hospital, Mr. C. I. Haden, delivered an address in which he described the development of the Trowbridge hospital service since its foundation in 1870. He remarked that the present building could now hardly be fitly called a cottage hospital, and it would be, therefore, known in future as the Trowbridge and District Hospital. The total cost of erection was approximately £16,000, and an additional £1,100 was required for equipment. Towards this £16,800 had already been received. As regards the cost of maintenance, it was hoped to increase the list of subscribers and also to establish a contributory scheme in the district. An address was given by Mr. H. S. Souttar, surgeon to the London Hospital, who congratulated the committee on the excellent buildings it had provided. He described the progress of hospital development through the ages, since the temples of Saturn were used to house the sick some 6,000 years ago. The modern hospital had come to be the last word in efficient organization, and the time was passing when it could be limited to the service of one class. Hospitals, he added, ought to be open to the whole community, since sickness made no distinction between poverty and riches. A great tradition was enshrined in the hospital system of this country, and Mr. Souttar looked forward to the time when these institutions would serve as a refuge for the nation, all the resources of the healing art being freely open to anyone in need of them.

Disposal of London Refuse.

Mr. J. C. Dawes's report of an investigation into the public cleansing service in the Administrative County of London was in effect an exposure of an intolerable failure to deal with a matter closely affecting the public health in a manner worthy of a great city. An interesting discussion of the situation disclosed in his report, and of his proposed remedy—namely, the creation of an *ad hoc* authority representative of the vast number of local sanitary authorities which in the aggregate go to the making of Greater London—took place on September 25th at a conference at the Middlesex Guildhall, Westminster, which was attended by representatives of the county councils of Middlesex, Essex, Buckinghamshire, Hertfordshire, and Kent. A preliminary notice of this conference appeared in last week's issue at page 603, and a discussion of the report itself in our issue of April 20th at page 734. Alderman H. R. Brooks, chairman of the Essex County Council, who presided, said that the dumping by the metropolitan boroughs of London of millions of tons of household refuse on the north shore of the Thames and at various places within the county of Essex had become an intolerable nuisance. One of the dumps was already 90 feet high, and spontaneous combustion had generated clouds of smoke and a nauseating smell which had drifted to the village of Rainham. The development of the London County Council estate at Becontree and of the industrial area north of the Thames was driving the population nearer and nearer to these insanitary areas, and the position had already become very serious. No local authority should be permitted to create such a nuisance within the area of another local authority. Some of the metropolitan boroughs had provided dust destructors and were able to deal with their own refuse without causing annoyance. Others simply made arrangements with a contractor, who took their refuse, and then did not care what became of it. The local authorities affected would do well, for their own protection, to consider the need of unitedly bringing pressure to bear on the Government. Mr. D. Crawford (Hertfordshire) said that proposals to be submitted to the Departmental Committee of Inquiry on behalf of the Hertfordshire County Council embodied the suggestion that no dump except for agricultural purposes should be allowed in any area without being registered and a licence being first obtained from the local authority of the area. The licence should contain such reasonable conditions as the Ministry of Health might approve, and there should be a right of appeal to the Ministry of Health if the licence was unreasonably withdrawn or withheld. Dr. A. Greenwood (medical officer of health for Kent) stated that in almost every area where the by-laws had been adopted and enforced rigidly the dumps had practically ceased. He did not like the proposal to make an exception for agricultural purposes; it might result in loopholes. Dr. J. Tate (medical officer of health for Middlesex) expressed his agreement with these views, and said that there were many differences of opinion as to what would constitute safety with regard to a dump. If it were possible to adhere strictly to precautionary measures drawn up by the Ministry of Health as by-laws a great deal of the offence of dumps would cease. Finally, the meeting agreed to the following resolution:

> That in the opinion of this conference a local authority should not be permitted to deposit by its servants, agents, or contractors refuse or other rubbish outside its own area without the previous approval of the county council and the district council within whose area the refuse or rubbish is deposited, and subject to such conditions as may be prescribed by such councils; this restriction not to apply to ordinary stable manure sent direct to a farm for agricultural purposes. In the event of a county council or local authority refusing consent an appeal to be made to the Minister of Health, whose decision shall be final.

Correspondence.

Mr. F. T. Paul.

Sir,—I see in to-day's *British Medical Journal* that in the Section of Surgery, at Manchester, Dr. William J. Mayo of Rochester, Minnesota, spoke of "the late Mr. F. T. Paul." About a month ago I had a long conversation with Mr. Paul in his garden at Caldy, and he was certainly then very much alive. It seems strange that no surgeon present at the meeting corrected such an obvious error. I hope it will be a long time before Mr. Paul gives me an occasion to write an appreciative obituary notice. Possibly he may be saying the same for myself.—I am, etc.,

Hindhead, Sept. 28th. James Barr.

*** We hope Mr. Paul will accept our sincere apologies for the editorial oversight.—Ed., B.M.J.

The Dressing of Wounds.

Sir,—In your interesting review of Dr. Orr's book on *Osteomyelitis and Compound Fractures and Other Infected Wounds* (September 21st, p. 540) you relate his methods of rest by skeletal fixation *without antiseptic dressings*, and his sang-froid in the presence of putrefaction under his vaseline-gauze dressing, even if the "discharge oozes out of the end of the plaster cast" and stinks.

Dr. Orr claims, we are told, to be a disciple, not only of Hunter and Hilton, but of Lister too. Of Hunter, I suppose, because his methods imitate Nature's; of Hilton because he gives diseased parts rest; but of Lister on the narrower and partial ground that the healing that takes place under the vaseline pad is comparable to that of Lister's first case of treatment of compound fracture under a scab of carbolic acid and blood. "He is a reasonable cleanly man, considering the scabs he has to deal with"[1] was Earle's vignette of the surgeon of his day (1628): I fear we shall lose even that lukewarm approval if the wounds we dress stink.

The acceptance of the principle of rest to the surface of damaged tissues on which Dr. Orr insists seems jeopardized, and jeopardized unnecessarily, by his disregard of putrefaction in the wound discharges; can that not be prevented without loss of the principle? In the little hospital where I work I use what goes by the name of "a peaceful picket"; it is a wet antiseptic dressing put over a piece of plain sterile gauze. Should the discharge soak through this plain dry gauze it reaches the antiseptic. We trust to the chemical to picket this open gate

[1] *Microcosmography, or a Piece of the World Characterized.*

(the discharge-soaked tract) against the entry of germs. That was Lister's method: "All we require," he said, "is that the dressing should be able to prevent the development of organisms from without into the discharges with which the dressing may be soaked."[1] Lister sought for a more suitable chemical than carbolic or the sublimate; Nowadays there is a great range of choice; and those that act in vitro must be best. Some of the dyes, such as flavine, do this; but what is especially desirable is a drug which will prevent the "odor" of which Dr. Orr speaks, and flavine in this respect runs second to tri-chloro-phenyl-methyl-iodo-salicyl, or "T.C.P." for short.

Healing by scabbing is always a problem. The opposite condition, "the clean granulating surface" which can be daily freed from pus, gives the satisfaction that nothing is hidden. But the daily dressings disturb what the scab protects—the growing skin, the vulnerable tissues. I have tried, in a small way, the experiment of dressing a raw surface by a homely method, based on Lister's practice, which may be described as an artificial scab. It is this: a thin piece of material, such as thin bandage cloth, is boiled in very strong tea—a readily improvised solution of tannic acid. It is cut a little larger than the surface to be healed, and applied so as to cling to it. A "peaceful picket" of gauze wrung out in "T.C.P." is put on top (with or without dry gauze intervening, according to the degree of sepsis). Only the gauze is changed. The material next the wound is left in place, and day by day is merely drenched with tea. A tanned scab is formed which falls off when all is healed.

For burns and scalds this way is useful, and as soon as discharge ceases the tea alone is used and the "picket" omitted. I am, etc.,

LIONEL JAS. PICTON.

Holmes Chapel, Cheshire, Sept. 25th.

PROPHYLAXIS OF POST-OPERATIVE THROMBOSIS.

SIR,—In a letter on this subject published in the *Journal* of July 27th (p. 166), Dr. R. Chalmers discussed the biochemical changes in the blood of patients recently subjected to operation. I made a study of the coagulation time of patients before and after operations in Professor Wilkie's wards of the Royal Infirmary, Edinburgh, using Cobb's coagulometer. A shortening of coagulation time was found in 80 per cent. of 157 cases; it was most marked immediately after operation, persisted for a few hours, and was not present on the third, fourth, and eighth days after operation. In 34 cases examined during anaesthesia a constant shortening of the coagulation time was found during or after the "excitement stage." On the 20 per cent. of cases which showed no change or an increase in coagulation time after operation many were associated with minor operations involving little trauma of tissue, or performed under twilight sleep or local anaesthesia. The greatest shortening of coagulation time was found after laparotomies and radical breast operations.

Two cases of femoral thrombosis occurred and one of fatal embolism. During the course of the thrombosis the patients showed a shortening of the coagulation time, but on recovery in both instances it was distinctly longer than normal average. Details of the fatal case may be of interest.

A married woman, aged 52, underwent the operation of gastro-enterostomy for duodenal ulcer. She had had one normal confinement, and three operations on the uterus. The coagulation time, before gastro-enterostomy, during the operation, and immediately after, was as follows:

	Coagulation time
Latency before operation	2 min. 25 sec.
(Normal	2 " 25 ")
Before beginning operation, 11.35 a.m.	2 " 0 "
(Normal	2 " 20 ")
Induction (Chloroform and Ether)	
11.36 a.m.	1 " 55 "
11.42 "	2 " 0 "
12.50 "	1 " 45 "
[illegible]	1 " 50 "

[illegible] progressed favourably. The temperature was 98.8° on the [illegible]

[1] "An Address on Germicidal Methods and Agents," *Lancet*, 1893, vol. ii, p. 1; *Collected Papers*, vol. ii, p. 100.

and fifth evenings, and again on the ninth evening. At 9 p.m. on the ninth day she complained of numbness of the left leg. At 1 a.m. she awoke, and again complained of numbness. While the nurse was moving the pillow under her knees the patient suddenly collapsed, and died in half an hour. At the post-mortem examination the upper branch of the left pulmonary artery was found to contain an embolus, and in the left internal iliac vein there was a long mixed clot, which was not adherent. There was also primary pulmonary thrombosis at the base of the right lung.

During an operation several conditions are produced, which, by calling forth adrenalin from the suprarenals, would cause increased coagulability of the blood. These are: (1) fear before the operation and excitement during the induction stage; (2) operative procedures under light anaesthesia; (3) asphyxia; (4) direct action of the chloroform or ether on the suprarenals; (5) low blood pressure, shock, or severe haemorrhage.

Some local thrombosis must occur after all operations, and substances liberated from the wounded tissues may so alter the coagulability of the blood that it begins to clot in vessels where there is stasis, or where a churning movement is produced by tributaries joining large veins, or where there is excess of carbon dioxide, as in the dependent parts of the lungs. Now all these factors are at a maximum either during or very soon after the operation; and this accounts for the fact that, although the most common time for pulmonary complications to follow thrombosis is during the second week, when movements are freer, and a piece of clot being in a friable stage may become detached, fatal pulmonary embolism has ensued within twenty-four hours of the operation.

Certain writers have remarked that post-operative embolism occurs in small epidemics, and might almost be said to have a seasonal incidence, with a maximum in February and March, in June, and in October. I have noticed during routine examinations of coagulation times that at certain periods all the pre-operative and normal control readings were short. (The normal average was 2 min. 40 sec. at 30° C.) During one of these periods (March 15th to 21st, 1927) one of the patients with femoral thrombosis had her operation, and a case of primary pulmonary thrombosis after an operation for cataract under local anaesthesia was seen in the post-mortem room. It was during another such period (May 23rd and 24th, 1927) that the fatal embolus case was operated upon, along with one other patient who also showed a very marked shortening of coagulation time after operation.—I am, etc.,

SIDNEY E. CROSKERY, M.D.

Tunbridge Wells, Sept. 28th.

THE PLANTAR RESPONSE IN HYPOGLYCAEMIA.

SIR,—Dr. Hawthorne in his letter on September 14th (p. 516) invites the recording of further cases of coma due to hypoglycaemia in which the extensor response has been noted. In the only case of hypoglycaemic coma in which I have examined the plantar responses these have been extensor. The blood sugar was 0.025 in this case; on return to consciousness the response became flexor. In cases of hypoglycaemia not reaching the stage of coma I have never found extensor responses. The plantar response was flexor in one case in which hypoglycaemia produced a severe confusional mental state and the blood sugar fell to 0.024.—I am, etc.,

A. W. CURTIS.

London, Sept. 30th.

RACIAL INCIDENCE IN DISEASE.

SIR,—In the *Journal* of September 14th sundry references are made to questions of race or type and their alleged morbid proclivities. Dr. M. Sonnsky (p. 513) challenges the allegation that there is a greater frequency of adenoid- among Jewish children, and Dr. Gray Hill and Miss Mary Allan (p. 499) furnish statistics to prove that a so-called rheumatic type is non-existent. It appears to me that, in most arguments against morbid proclivities being associated with a particular race or type, an essential factor is omitted from the premisses—namely, the environment that evokes the alleged proclivity.

It will hardly be need [illegible] in Greenland or a settlement of Eskimos on the Coast, each will exhibit in even degree morbid proclivities which the natives amongst whom they have intruded [illegible]

correctly regard as "racial" in character, seeing that they themselves suffer from them little or not at all, being harmoniously adjusted to their surroundings. It is undeniable that the Negro, with his gaping nostrils and peculiarities of skin, as regards its pigment, vascularity, and gland supply, has physical traits correlated with the climatic conditions in which he evolved. He is a highly differentiated type, and so is the Eskimo; each will exhibit inability to adapt to a major degree of change in environment.

But can it be maintained that between such gross disharmonies and a state of perfect adaptation to environment no minor or intermediate degrees of maladjustment exist? For example, do the "Caucasian" and the Mongol not exhibit signs of maladaptation peculiar to their type in surroundings differing from those determining the evolution of their characteristic traits? This, also, is undeniable.

What about the Nordic, the Jewish, the Alpine, the Mediterranean types? Are their distinctive features not to be correlated with the conditions of their evolution, or is their adaptability so perfect that migration to the land of the stranger evokes no typical reaction? Proceeding from them, consider the less clearly defined but still distinguishable types, physical or mental, such as those who are termed in our own land North-, South-, East-, or West-country folk, or such as spring from little rural communities, long inbred, and thereby *specialized for local conditions*, including soil, atmosphere, and occupation. Is it not probable that they also will manifest recognizable disabilities and proclivities proportionate to the *degree* of discordance of their present environment with that in which their particular type was evolved?

I have been asking for research on these matters for many years, and have adduced examples, from my own experience and that of other observers, seeming to warrant the comprehensive investigation needed finally to establish or disprove the truth of my contention. I repeat that it is futile to inquire whether this, that, or the other racial type or subtype evinces this, that, or the other morbid proclivity, unless such alleged proclivity *is correlated* with the environment—tropical, temperate, arctic; dry or humid atmosphere; urban, suburban, or rural; nutritional, psychical, etc. In which signs of disharmony or disease appear.

Taking "rheumatism," for example. There are two environmental conditions of almost diametrically opposed character which appear to favour its onset. One is damp associated with cold; the other is drought and heat when the air is full of germ-charged dust such as, for instance, has occurred during the past summer, when rheumatism in various forms has been very prevalent. I should like to know whether more "non-pigmenters" develop rheumatism in the one condition and more "pigmenters" in the other. I believe that I have observed the cold and damp conditions to be specially noxious to non-pigmenters, but I have a mind open to correction.

Then, regarding the Jews; a considerable proportion of my practice has been among them during the past thirty years. I sought an explanation of what appeared to me their disproportionate proclivity, *compared with* my other patients, to catarrhal infections, and, what is so closely linked up with them, enlarged tonsils *and adenoid* growths. This observation was made with the opportunities afforded by the intimacy of family practice. It occurred to me that the explanation lay in the fact that the Jewish type was evolved *in a warmer and dryer climate* than that of North-West Europe an evolution of many thousands of years' duration. Their proclivity to enlarged tonsils, adenoids, and catarrhs in general was therefore a sign of imperfect adaptation to their present environment. On the other hand, the Jews' experience of urban conditions has been very much longer and more severe than that of our average urban communities, and in this respect they evince superior adaptation.

It was this consideration of the Jews that started an inquiry on my part whether other intrusive types Nordic, Alpine, etc. also showed signs of imperfect harmony with conditions in this country, and, from this, the effect of intramigration and urban immigration on our rural types. Those who care to follow up the matter will find references to it in papers in the *New Age*, June 1-8, 1911, *School Hygiene*, September, 1911; *Clinical Journal*, August 9th, 1911; *British Medical Journal*, August 17th, 1912, and August 2nd, 1913; *Lancet* (letter), June 10th, 1916; and *Medical Press and Circular*, 1919 20.

I should add that the *scope* of my inquiry has not been so much the fact, already noted by Beddoe, Shrubsall, Woodruff, and others, that certain types appear to evince certain morbid proclivities; my endeavour has been to ascertain why they do so in this country and in what circumstances.—I am, etc.,

J. STEWART MACKINTOSH, M.D.,
Fellow of the Royal Anthropological Institute.

London, N.W.3, Sept. 21st.

CO-OPERATION BETWEEN PRIVATE PRACTITIONERS AND HOSPITALS.

SIR,—Writing as a private practitioner and *from experience of the system* at present in vogue at the Royal Free Hospital, which Mr. Joll mentioned in his letter on September 28th (p. 598), I consider the forwarding of the case-sheet to the patient's private doctor would meet most of the requirements. It seems that in most of the London hospitals at present we have to depend for our information on communicating with the house-surgeon. Every practitioner knows how difficult it is to get a house-surgeon on the phone: he is either engaged at an operation or busy in the out-patient department, etc. When we do eventually get in touch with him it is quite possible that he is not the one who admitted our patient, or in charge of him, and consequently can tell us very little. We can only hang up the receiver and repeat the process later on, when we may be again unlucky. It would be both unjust and unfair to expect the consultant staff to reply personally to each doctor's letter that accompanies a patient. If the hospital authorities could provide some means whereby the salient features of the patient's case-sheet could be transferred to his private doctor it would greatly stimulate the latter's interest and knowledge, and would be deeply appreciated.—I am, etc.,

JAS. E. AMBROSE.

London, N.1, Sept. 29th.

SIR,—There would be no more complaints by private practitioners against hospitals as regards lack of co-operation if the excellent plan adopted by the Ear, Nose, and Throat Department, Bristol Royal Infirmary, were universally adopted. In all cases, whether in-patient or out-patient, one receives a letter with full notes under the appropriate printed headings—"diagnosis," "clinical findings," "suggested treatment," "prognosis," etc. In addition to this, and added underneath the address of the department, are the days and hours of attendance, details which are apt to escape the memory of the busy practitioner, to whom this reminder is a ready aid. I expect the Bristol Royal Infirmary is every bit as busy as any other hospital, and if the procedure set out above can be carried out in that institution, there seems to be no reason why it should not obtain in all hospitals. At any rate, *I have found it a great boon*, and never neglect to acknowledge these letters with my most grateful thanks.—I am, etc.,

September 30th. SOMERSET PRACTITIONER.

MATERNAL MORTALITY.

SIR, At the National Conference of Friendly Societies held at Lowestoft *this week* more than one speaker referred to the gravity of the death toll of motherhood, and one *mentioned* the fact that there had been no reduction in the death rate among mothers during the last twenty years. *It is high time* that the general practitioner asserted himself, for, until he does so, this state of affairs will remain.

The question of maternal mortality and morbidity is one of *national* importance, and closely bound up with the question of infantile mortality and morbidity. The whole *profession* is concerned, but the solution of the problem is intimately within the province of the general practitioner; given the chance, it is he, and he alone, who will reduce the death rate of mother and child.

Every lying-in woman should, by law, have a qualified medical practitioner in attendance; she should not be left to the care of the army of badly taught and badly trained women, many of whom are launched on the long-suffering community after a short stay in hospital. They have ousted the good old-fashioned "handy woman who followed the doctor"; she did as she was told, and knew by experience and not by making unnecessary vaginal examinations when to send for medical help.

The midwife of to-day is taught to use strong antiseptics, and she has not the first idea of asepsis. She imagines because she has rinsed her hands in a strong antiseptic solution that her fingers are clean enough to make a vaginal examination. She introduces her fingers laden with a corrosive solution, which causes pain in nine women out of ten, and destroys the vaginal flora which, with the natural secretion of the vagina, are there to protect the parturient woman against the invasion of septic organisms. These midwives are not content with one examination, and the law is on their side. One sequel is the raising of an army of women to keep an eye on midwives; they are a burden on the rates, and their sole occupation apparently is collecting statistics to swell the annual report of the M.O.H. This army has to be officered, and the staff of the M.O.H. is swelled to bursting point with highly paid assistants with no experience of general practice—another burden on the ratepayer.

The present-day midwife too frequently fails to send for a doctor to suture a ruptured perineum; consequently a broad highway is left for the entrance of septic invasion. The day will come, and it should come soon, when it will be an indictable offence for any person other than a qualified medical practitioner to make a vaginal examination in a pregnant woman. The matter is too serious to be long delayed, for, not only is the maternal death rate not diminishing, but the survivors too frequently are left with a legacy of ill health, and are either unable or unwilling to bear further children.

Here is an extract from a letter I have received from a retired practitioner.

"I do not think that maternal mortality has been reduced enough since I began in 1878. Then there were scarcely any precautions taken. We did not even wash our hands before an examination. For lubricating the fingers or forceps—if in a farmhouse a dab of saltless butter was used—any old oil or grease that was handy was utilized. When the case was managed by the so-called midwife, the soiled nightdress, flannel petticoat, etc., and the underlying blanket were left undisturbed for three or four days, irrespective of the amount of blood, liquor amnii, etc., that saturated these things. Imagine the effluvia! and, as fresh air was excluded as much as possible, and the *room darkened* according to custom, you can also imagine what an unhealthy condition existed. Yet, as a rule, *the patient got on all right.* Even when there had been rough interference—say, craniotomy, or difficult turning—*the patient generally did well.* Chloroform was hardly ever used, forceps not often needed, laceration of the perineum seldom happened, lactation was sufficient for nine months or more—and now, with all the improvements in the conduct of labour, etc. etc., things are still bad. Labour seems to be more tedious, more difficult, necessitating an anaesthetic almost always, and the very frequent use of forceps. Few can give the breast, even the willing ones, for more than a month or two. . . ."

These were the days, too, when the doctor, generally after imbibing freely, fell asleep at the bedside with two fingers in the vagina, to be aroused by the gush of liquor amnii when the membranes ruptured—and the patients "generally did well"! And why? The natural secretions were undisturbed, the birth-canal was flushed by liquor amnii, swabbed by the child, and sponged by the afterbirth. Lacerations were rare, and it is through lacerations, internal or external, that infection takes place.

The remedies, therefore, are clear.

1. A doctor must be present at every confinement.

2. He must remember, after scrubbing with antiseptics in the usual way to get his hands surgically clean, to rinse them in sterile water before making an examination in order to remove all trace of antiseptics, unless he is using gloves sterilized by boiling.

3. The external genitalia may be swabbed, but on no account must the vulva or vagina be subjected to any treatment whatsoever.

4. All lacerations, however small, must be sutured, and iodine freely used afterwards.

5. Most important of all, every effort must be made to lessen exhaustion by the judicious use of all the appliances at our disposal.

All our efforts to-day are directed to the alleviation of the pain and suffering that every lying-in woman is heir to. To quote from *Then and Now in Midwifery*, by Dr. W. J. Young:

"Prior to 1847 the experience of womankind throughout the ages may be likened to a toilsome, interminable journey through a morass of pain . . . and so at last the Then began to pass away before the dawn of Now, when in 1847 anaesthesia came to be administered to alleviate the pains of maternity. Simpson himself wrote early on, 'I have now seen an immense amount of maternal pain and agony saved by its employment'; and the triumph of chloroform was assured by its administration to Queen Victoria in 1853."

Axis-traction forceps, twilight sleep, and now the administration of ovarian residue, have all been thought out with that one end in view—the alleviation of this terrible suffering. By lessening the pain and shortening the duration of labour we are going to produce a stronger and a healthier motherhood and a stronger and a healthier race of children. There will no longer be the dread of having to go through a long and tedious labour after nine weary months of ups and downs in health. Succeeding pregnancies will be entered into without a qualm, and the State will benefit, not only by the raising of an A1 population, but by the definite increase in population which will ensue.—I am, etc.,

D. C. MACDONALD, M.B.

Blackley, Manchester, Sept. 29th.

THE DIAGNOSIS OF ANAEMIAS BY MEANS OF DIFFRACTION.

SIR,—In the *British Medical Journal* for July 13th (p. 48) Dr. Frank C. Eve of Hull published a paper entitled "The early diagnosis of pernicious anaemia by the halometer." The paper deals with a method and an instrument for the quick measurement of red blood cells by using a blood smear as a *diffraction grating.*

The method described by Dr. Eve is a simplified and distorted version of the diffraction method of measuring red cells which I discovered in 1918.[1] As soon as Hurst's memorable paper on pernicious anaemia appeared in the *British Medical Journal* I applied the method to the diagnosis of pernicious anaemia.[2] Subsequent to the publication of my earlier papers, I have learnt that Thomas Young used the identical principle, with a different technique, for purposes of measurement, but, of course, there was no question of differential diagnosis of anaemias in his time.

Since I first introduced the diffraction method of diagnosing anaemias I have considerably improved the method by designing a technique which facilitates measurements, increases sensitiveness, and widens the scope of the method. It is now possible to determine simultaneously the average diameter of a million cells, the degree and quality of anisocytosis present by measuring the larger and smaller cells, and the degree of poikilocytosis. A full account of these improvements was quite recently given by me in your columns.[3] Dr. Eve in his paper disregards the history of the diffraction method as a diagnostic measure. He presents it as an entirely new and original method of his own. He leaves out all references (except one, and that is a reference to another apparatus of his own design, this time for the sucking of tonsils). Though he does me the honour of mentioning my name in connexion with a certain feature of the theory, he gives no reference to my work on the subject, and completely ignores improvements recently introduced. His apparatus is based on an incomplete and incorrect interpretation of the theoretical foundation underlying the method as described by me many years ago.—I am, etc.,

Obituary.

ERNEST E. GLYNN, M.D., F.R.C.P.,

Late Professor of Pathology, University of Liverpool, and Honorary Bacteriologist, Liverpool Royal Infirmary.

The news of the death of Professor Ernest Glynn on Sunday, September 22nd, did not come as a surprise to his friends. For many years he had suffered from diabetes mellitus, and latterly complications had supervened so serious that two years ago he was obliged to resign from the chair of pathology at the University of Liverpool.

Ernest Edward Glynn was born at Liverpool in 1873, the son of Dr. T. R. Glynn, who is still emeritus professor of medicine at the University of Liverpool. At an early age he must have felt the supreme attraction of medicine as a scientific study, and the intense satisfaction from its pursuit as an art. To such a mind, imbued with high ideals of duty and service, it was natural that religion in its more formal aspect would make an irresistible appeal. It is not surprising, therefore, that on entering Clare College, Cambridge, in 1892, Glynn set himself to read for the theological tripos. A year later, however, he decided that natural science would more completely satisfy his emotional and intellectual needs, and from this time to the end of his life he never faltered in its service. From the study of science to the more human and less academic one of medicine is an almost natural transition for a man of Glynn's temperament, and in 1898 he obtained the diplomas M.R.C.S., L.R.C.P. before graduating M.B., B.Ch. at Cambridge in 1901. Three years later he became M.R.C.P.; in 1909 he graduated M.D.Camb., and in 1913 was elected F.R.C.P. Having served as house-physician at the Royal Infirmary and as Holt Fellow in Pathology at the University of Liverpool, in 1902 he began his career as a consulting physician by being appointed to the staff of the Liverpool Hospital for Consumption. Two years afterwards he was elected honorary assistant physician to the Liverpool Royal Infirmary.

At this point in his career the fates began to weave a web which was to draw the young consultant from his appointed path, and irrevocably entangled him, not unwilling, in the pursuit of pathology. Owing to the indifferent health of Sir Rubert Boyce, then professor of pathology, Glynn was called upon to act as his deputy from time to time. In April, 1906, he was obliged to take six months' holiday on account of an infection contracted in the post-mortem room. On his return to work in October the University again requested him to take charge of the pathological department. His medical advisers forbade him to undertake this duty in addition to his work as physician to the Royal Infirmary. Glynn, realizing that a man cannot serve two masters, resigned his position at the Royal Infirmary, and from henceforth he devoted himself entirely to pathology. He was immediately appointed deputy professor, became associate professor in 1910, and, on the death of Sir Rubert Boyce in 1912, was given full charge of the department. In the course of time he became honorary pathologist to the Royal Infirmary, and consulting pathologist to the Northern Hospital, the Children's Infirmary, and the Hospital for Women. During the war Professor Glynn served in the R.A.M.C. with the rank of captain, and was responsible for an immense amount of valuable routine and research work. As one of the chief pathologists in the Western Command his services were in constant request during the great epidemics which took place at this time.

Professor Glynn and the workers in his laboratory carried out researches of considerable importance; much of the work only a pathologist is competent to discuss and assess, but not a little has proved of general interest to the whole medical profession. With hypernephromata and their connexion with the production of secondary male sex characteristics the name of Glynn will always be associated. That surgical tragedy, pulmonary embolism, and its attendant problems constantly occupied his mind. His contention that the condition was not embolic but rather a primary thrombosis in the lung vessels has received much support, but the final solution is not yet. His laborious researches on the bacteriology of pneumonia are too technical for discussion here, and the same applies to his work on blood grouping. His last contribution to medical science dealt with the Wassermann reaction. His intense labour on this subject, which seemed to take possession of his mind to the exclusion of nearly all else, was not without causal connexion with his final breakdown. As the result of his most careful and critical study of a large mass of statistics he came to the surprising conclusion that Wassermann negative syphilitic patients treated with continuation courses of mercury relapsed more often than those who received no continuation treatment at all. It was no little disappointment that this really remarkable result received relatively slight attention at the hands of syphilologists. Before leaving the purely professional side of Professor Glynn's activities, mention must be made of his remarkable inventive skill. The best example of this was the machine for the mechanical distribution of measured amounts of fluid from a series of glass syringes. The speed and accuracy of this machine is wonderful, and as a labour-saving device it merits more extensive employment. He was never happier than when engaged upon some new mechanical invention, and had he been of a commercial turn of mind one could almost imagine the slogan appearing on advertisement hoardings, "Glynn for gadgets."

As a teacher Professor Glynn will never be forgotten by his old students. His intense and forcible delivery, coupled with an admirable dogmatism, impressed even the most listless of his audience with the weight of his remarks, so that to forget was wellnigh impossible. A delightful caricature, drawn for the menu card of one of the medical students' annual dinners, depicted him in post-mortem apron holding a dripping specimen in one hand and with the other beating time to the refrain "For Heaven's sake don't forget typhoid." No mere academic life, however full, could satisfy the intense humanity of Professor Glynn. Throughout his life a very real interest and active participation in practical affairs was evident. As a student he was president of the Liverpool University Guild of Undergraduates; for many years he filled the office of honorary treasurer of the Athletic Club, and was also a prominent figure in the Old Students' Association. The Liverpool Medical Institution, the Pathological Society of Great Britain and Ireland, and many other centres of activity found in him a supporter whose place will not be filled. In this connexion, too, one must mention another characteristic of the man—his intense love for his country. This was prompted by no flag-waving spirit of jingoism, but by a deep reverence for what England had meant in the history of the world, and by an intense optimism for the future. In this sense he was a politician.

One can enumerate in cold words this and that side of his personality, but always there will remain in the memory of his more intimate friends those delightful informal gatherings which took place in his laboratory every afternoon. Here would come old students home on leave from all parts of the Empire, and over a cup of tea old friendships would be renewed and new friendships made. Presiding over such happy gatherings as these one will remember the kindly spirit of our old teacher and friend. These cherished memories are a memorial in our hearts to Professor Glynn. He would have it so.

A. Douglas Bigland.

We are indebted to Professor A. E. Boycott, F.R.S., for the following appreciation:

Glynn was originally a clinician, and it was more or less by accident that he succeeded Rubert Boyce as professor of pathology in Liverpool. His training had been comprehensive: morbid anatomy, general pathology, and bacteriology were all of interest to him if they threw any light on disease, and the exceptional range of his original inquiries reflects very well his attitude towards pathology. That suprarenal tumours are now successfully removed by surgeons from women who show sex changes is chiefly due to his calling attention to the association, and so making diagnosis possible. The work on the changes in the blood platelets after operations which has lately come from the Liverpool laboratory, and on the quantitative aspect of isohaemagglutinins, illustrate his studies in general pathology

to the academic pathologist, Glynn conceived them as illuminating respectively post-operative thrombosis and the dangers of transfusion. In bacteriology he dealt with dysentery bacilli, pneumonia, the meningococcus, pyorrhœa, and in earlier years with the opsonic index and methods of counting bacteria; he made good use of the mass of records of the venereal diseases clinic in evaluating the advantages (apparently negative) of giving mercury in addition to the arsenicals. It was since the war that Glynn's powers as an investigator developed and ripened; in the last few years, before he broke down in 1927, his industry and effectiveness were really remarkable, not only in his own work, but in the teaching of his students and the stimulation of young graduates. His classes in pathology reached a standard which is seldom achieved; his keen dogmatic teaching gave an admirable immediate result, and roused an interest which bore fruit in many good M.D. theses. Unmarried, with few or no interests outside his department, he gave his heart to pathology, and his influence was always for good.

Professor J. Lorrain Smith, F.R.S., dean of the Faculty of Medicine in the University of Edinburgh, writes:

When Professor Ernest Glynn was appointed to the chair of pathology in Liverpool he had already held the office of assistant to Sir Rubert Boyce. Sir Rubert had given much time and energy to the movement for the expansion of the medical school, but he did not live to see more than the early result of his labour. Glynn took up the duties of the chair with great zeal. Like his predecessor, he had a strong conviction of the value of pathology in the medical curriculum. His aim was to present the subject to the students so that they could not fail to see the necessity for a competent knowledge of the subject. The secret of his success as a teacher lay in his profound knowledge of pathological principles and his rich experience of their application in practical medicine. The time left when his official duties were done was spent in research. His toil was unremitting, and the amount of work he was able to carry out was an inspiration to all his colleagues. Yet he was ever modest in his estimate of what he had accomplished, and when an investigation had been completed and published he would quietly remark that he feared he had not been able to do all that was required to secure the full results the inquiry should have yielded. To a great variety of subjects he made contributions which, by the thoroughness and accuracy of his observations, made him an outstanding authority. He covered a wide field in both human and comparative pathology and bacteriology.

He was an original member of the Pathological Society, and in the committee, and later as treasurer, he took an active part in its proceedings. His contributions to the agenda were always welcomed, and the debating to which they gave rise was a real gratification to him. When it came round to his turn to conduct the meeting of the society in his own department there was a large gathering of the members. The agenda was full of interest, and the members found that he had spent such care in arranging details that the visit to Liverpool was a memorable event. When he could spare time for a holiday he was a genial companion, keen to take part in holiday pursuits, but he was apt to be called back to work before he had had the relaxation which the holiday should have given. While he was working to the utmost of his powers his health failed, and though he rested he was not restored. His friends and colleagues will cherish the memory of his personality—genial, loyal, and steadfast, and devoted to the highest ideals.

The following well-known foreign medical practitioners have recently died: Professor Toby Cohn, a Berlin neurologist; Dr. Walter Hövz, an eminent Breslau surgeon; Dr. Capitan, professor at the Collège de France and member of the Académie de Médecine; Dr. Eduardo Semprun y Semprun of Madrid, inspector-general of the health services of the Spanish army and director of the Technical Institute of Military Hygiene; and Dr. Aletty Jakobs of Amsterdam, the first Dutch woman practitioner, aged 79.

Universities and Colleges.

UNIVERSITY OF LONDON.

Three lectures, on (1) seasonal variations of epidemic diseases, (2) milk epidemics, (3) diphtheria toxin and antitoxin, will be given by Professor Thorvald J. M. Madsen, Director of the Statens Serum Inst[illegible] the London School of Hygiene and Tropica 14th, 16th, and 18th, at 6 p.m. Dr. Andrew Director of the London School of Hygiene, lecture.

A course of four lectures on secretion of the digestive juices will be given by Dr. R. J. Brocklehurst at University College, Gower Street, W.C.1, on October 14th, 21st, and 28th, and November 4th, at 5 p.m.

Four lectures on metabolism of the carbohydrates and fats will be given by Dr. J. A. Hewitt at King's College, Strand, W.C.2, on October 17th, 24th, and 31st, and November 7th, at 5 p.m.

Professor V. H. Mottram will give a course of six lectures on human nutrition at King's College for Household and Social Science, Campden Hill Road, W.8, on October 18th and 25th, and November 1st, 8th, 15th, and 22nd, at 5 p.m.

The Semon Lecture, entitled "The lower end of the œsophagus at birth and in the adult," will be given by Dr. Harris P. Mosher, professor of laryngology in the Harvard University, in the Barnes Hall of the Royal Society of Medicine on Thursday, December 5th, at 5 p.m.

Viscount Grey of Fallodon will deliver the Rickman Godlee Lecture on Thursday, November 7th, at 5.30 p.m.

Sir StClair Thomson will deliver a lecture, under the auspices of the King's College Medical Society, on Lord Lister: "Reminiscences by a house-surgeon," on Friday, October 11th, at 5.30 p.m.

The Geoffrey Duveen travelling studentship in oto-rhino-laryngology, of the value of £450, will be awarded annually. The tenure shall be, in the first instance, for one year, which will be spent in study abroad, in accordance with a scheme to be approved by the Geoffrey Duveen Studentship Board, but may be extended for one or two years; during the extended period the student may be allowed to undertake research at the Royal Ear Hospital or some other approved laboratory. Grants for the promotion of research in the subject of oto-rhino-laryngology, or any part thereof, may also be made from the trust fund of the benefaction. No person is qualified for election to the studentship or to receive grants from the fund until he or she has obtained the degree of M.B. and B.S. in the University. Applications must be made on prescribed forms obtainable from the Academic Registrar of the University, and should be sent to reach him by December 31st, together with a statement of the nature of the proposed research and a scheme of study submitted for the approval of the Board.

University College.

Farewell Dinner to Sir Gregory Foster.

Sir Gregory Foster, who retires from the position of Provost of University College, London, on December 31st, will be entertained at dinner by the past and present students of the College on Friday, December 20th. The dinner will be held in London, and the place will be determined when the number of those intending to be present has been ascertained. Past and present students who wish to attend the dinner are requested to notify Mr. B. N. Parker, honorary secretary, Old Students' Association, at the College, with as little delay as possible, and to add particulars of their Faculty and dates of student years.

UNIVERSITY OF LEEDS.

The following candidates have been approved at the examinations indicated:

M.D.—R. Chester, M. S. Scott, A. Sourasky.

Final M.B., Ch.B.—*Part I:* F. B. T. T. Drake, W. R. Everatt, G. Hirst, J. Rabinovitch, M. I. Silverton. *Part II:* W. H. Craven, H. Denton, C. H. Foster, W. L. Hardman, J. N. Hill, L. Hoyle, C. Poniedel, S. Rosenberg, L. Seaton, W. E. Smart, E. J. Wayne, J. W. Whitworth. *Part III:* E. J. Wayne (first-class honours), C. H. Foster (second-class honours), W. L. Hardman (second-class honours), T. G. Clarke, H. Denton, S. R. Foster, W. Greaves, L. Hoyle, H. T. Knowles, C. Poniedel, Margaret F. Robertson, Mary G. Shawe, J. W. Whitworth.

D.P.H.—Kathleen M. Peacock, Edith A. Whitney.

D.P.M.—C. L. Copeland, W. Fraser, D. T. Gemmell, J. J. O'Riordan.

The William Hey Medal for the most distinguished medical graduate of the year has been awarded to Mr. Edward Johnson Wayne, who has also received the West Riding Panel Practitioners' Prize for proficiency in medicine.

UNIVERSITY OF LIVERPOOL.

Liverpool School of Tropical Medicine.

The Mary Kingsley Medal, which is conferred in recognition of distinguished scientific achievement, has been awarded to the following gentlemen:

Dr. George Carmichael Low, Senior Physician to the Hospital for Tropical Diseases, London; Guy A. K. Marshall, C.M.G., F.R.S., Director, Imperial Bureau of Entomology; Emeritus Professor Robert Newstead, F.R.S., formerly Dutton Memorial Professor of Entomology, Liverpool School of Tropical Medicine; Dr. A. T. Stanton, Chief Medical Adviser to the Secretary of State for the Colonies; Emeritus Professor J. W. W. Stephens, F.R.S., formerly Professor of Tropical Medicine, Liverpool School of Tropical Medicine: Dr. C. M. Wenyon, C.M.G., F.R.S., Director-in-Chief,

[illegible] chairman of the school, Liverpool on October 11th.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—T. G. De V. Coneys, T. J. Gilmartin, W. C. B. Harrison, D. J. Mangan, P. F. Murray, J. F. O'Halloran, M. H. O'Reilly, H. D. Plunkett.
D.P.H.—Dr. E. J. Daly, Dr. A. B. Monks, Dr. T. V. C. Nolan, Dr. J. H. Owen-Flood.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following candidates have been approved at the examinations indicated:

PRIMARY FELLOWSHIP.—Dr. R. G. Krishnan, Dr. P. P. Chandu Nambiar, Dr. L. N. Ross.
FINAL FELLOWSHIP.—Dr. S. V. Furlong, Dr. J. Owens, Dr. R. R. Woods.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel William James Taylor, R.A.M.C. (ret.), died at Plaston, in the Transvaal, on July 1st, aged 64. He was born at Ballymoney, in Ulster, on August 27th, 1865, and was educated at Queen's College, Galway, and at the Carmichael College, Dublin, graduating as M.B., Ch.B., and B.A.O. of the Royal University, Ireland, in 1888. Subsequently, in 1908, he took the D.P.H. of the Irish Colleges, with honours. After filling the posts of demonstrator and lecturer in anatomy in Queen's College, Galway, he entered the R.A.M.C. as surgeon lieutenant on January 30th, 1893, became lieutenant-colonel on March 1st, 1915, and retired on March 20th, 1920. On the first appearance of plague in Bombay in 1896 he volunteered for plague duty, and was employed as a district plague officer in Bombay. He served in the Tirah campaign on the north-west frontier of India in 1897-98, receiving the medal with two clasps; and in the recent great war of 1914-18, when he was mentioned in dispatches in the *London Gazette* of June 15th, 1916.

Lieut.-Colonel Henry Haldane Stokes, R.A.M.C. (ret.), died at Oxford on July 6th, aged 82. He was born on September 11th, 1846, and was educated at Trinity College, Dublin, where he graduated as M.B. in 1869, subsequently taking the M.R.C.S. in 1872. He was the last officer commissioned as assistant surgeon in the army, which he entered on March 30th, 1872; the rank of assistant surgeon was soon after abolished, and he was promoted to surgeon from the day on which he entered as assistant surgeon, March 30th, 1872. He attained the rank of brigade surgeon lieutenant-colonel on July 9th, 1895, and retired on September 13th, 1902. He attained the rank employed at Oxford from 1902 to 1911. After his retirement he was Africa, in the Zulu war of 1879, receiving the medal with a clasp; and on the north-west frontier of India, in the Hazara campaign of 1891, when he was mentioned in dispatches in the *London Gazette* of October 20th, 1891, and received the frontier medal with a clasp.

Lieut.-Colonel Frank Edward Barrow, R.A.M.C. (ret.), died on August 7th, aged 79. He was born at Brecon on July 7th, 1850, the son of the late Inspector-General T. W. Barrow, A.M.D. In his childhood he accompanied his father to South Africa, and later to Montreal, where his father was senior medical officer, and went through his schooldays there. Subsequently he entered Guy's Hospital, and took the M.R.C.S. and L.S.A. in 1871. He entered the A.M.D. as assistant surgeon on September 30th, 1871, passing in two places above his brother, the late Colonel H. J. W. Barrow, and was posted to the Royal Irish Fusiliers, 89th Foot, being the last assistant surgeon posted to that battalion under the old regimental system. He became lieutenant-colonel after twenty years' service, and retired on January 25th, 1893. When on the retired list he was employed for a time at Woolwich, and later as principal medical officer of a general hospital in the South African war. He served in the Egyptian campaign of 1882 (medal and Khedive's bronze star); in the Sudan campaign of 1885, at Suakin (clasp); and in the South African war (Queen's medal with two clasps). His immediate family has contributed no fewer than five members to the A.M.D. and R.A.M.C. His father, Inspector-General Thomas Waller Barrow, entered on June 8th, 1841, served in the Kaffir war of 1852-53 and in the Crimea, retired in 1863, and died in 1900. His eldest brother, Lieut.-Colonel Thomas Samuel Barrow, entered in 1864, served in the Egyptian war, retired in 1884, and died last February. His twin brother, Colonel Henry John Waller Barrow, entered at the same time as himself, served in the Sudan campaign of 1885-86, retired in 1910, and died in 1923. His nephew, son of Colonel H. J. W. Barrow, is now Major General H. P. W. Barrow, C.B., C.M.G., D.S.O., O.B.E., K.H.S.

Medical News.

THE annual general meeting of the Medical Sickness, Annuity, and Life Assurance Society will be held at the First Avenue Hotel, High Holborn, W.C.1, on Monday, October 7th, at 4 p.m.

A SESSIONAL meeting of the Royal Sanitary Institute will be held on October 11th and 12th at The Castle, Shrewsbury, when discussions will take place on recent bridges over the River Severn; reconditioning of houses under the Housing (Rural Workers) Act, 1926; and the scope of a house property management department.

THE Liverpool annual medical service will be held in the Cathedral on October 13th, at 3 p.m.; the sermon will be preached by the Right Reverend E. C. Pearce, D.D., Bishop of Derby. Medical practitioners and their friends are cordially invited to attend, and tickets may be obtained from Dr. R. Kennon, 28, Rodney Street, Liverpool.

THE RT. HON. CHRISTOPHER ADDISON, M.D., M.P., has been appointed by the Prime Minister chairman of a committee to inquire into the question of establishing one or more national parks in Great Britain with a view to the preservation of natural characteristics including flora and fauna, and the improvement of recreational facilities for the people.

DR. ALLAN C. PARSONS, a medical officer of the Ministry of Health, has been appointed a member of the Departmental Committee appointed to inquire into the relief of the casual poor and to make recommendations having special regard to the assistance of persons genuinely seeking work and to persons suffering from physical or mental disability. The chairman of the committee is the Rev. L. R. Phelps, and the secretary Mr. L. N. Ure, of the Ministry of Health, Whitehall, S.W.1.

THE new session of the Torquay and District Medical Society will open on October 10th with a lecture by Sir Farquhar Buzzard on disorders of function. Dr. P. A. McCallum will deliver his presidential address on November 21st. Dr. H. Morley Fletcher will lecture in January on the prognosis and treatment of pneumonia, and in April Dr. John Freeman will discuss the present position of vaccine therapy. The programme for the session also includes a survey of some of the less common ear, nose, and throat conditions, a demonstration of neurological cases, a display of medical and surgical cinematograph films, and a debate on birth control. In addition, afternoon clinical meetings will be held at the Torbay Hospital, the Whitecliffe Hospital, and the Newton Abbot Hospital.

THE Fellowship of Medicine has arranged a series of weekly clinical demonstrations in medicine and surgery for the winter session. The first two will be given at the Prince of Wales's Hospital, Tottenham, on October 8th, at 2.30 p.m., by Dr. Browning Alexander, who will conduct a ward round, and on October 10th, at 2 o'clock, Mr. H. W. Carson will demonstrate in the out-patient department. From October 8th to 31st a series of lecture-demonstrations will be given on Tuesday and Thursday afternoons at the London School of Tropical Medicine. There will be a morning course at Great Ormond Street Hospital from October 14th to 26th, which will comprise work in all the various departments of the hospital. A course in gynaecology will be held at the Chelsea Hospital for Women from October 14th to 25th, comprising operations and lectures. A special all-day course in diseases of the throat, nose, and ear will be held at the Central London Throat, Nose, and Ear Hospital from October 14th to November 2nd, comprising clinical, practical operative (limited), and pathological classes. There will be an intensive course in medicine, surgery, and the specialties at the Metropolitan Hospital from October 21st to November 2nd. The Fellowship of Medicine has also arranged an evening course for the M.R.C.P., comprising sixteen lectures at the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, at 8.30 p.m., on Tuesdays and Fridays, from October 15th to December 6th; the opening lectures will be delivered by Dr. B. T. Parsons-Smith on October 15th and 18th. Copies of all syllabuses and information regarding the general course of work at the associated hospitals can be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

LECTURES to school audiences on the work of the London Voluntary Hospitals are being resumed by King Edward's Hospital Fund for London. The scheme has now been in operation for five years. Among the subjects treated are: "One day in the life of a hospital," "Modern methods of fighting disease," and "Science in the service of the hospitals." The lectures are given by doctors and others intimately associated with hospital work; they are educational, and no direct appeal for money is made in connexion with them. The King's Fund would particularly welcome an offer by any school with a suitable hall to act as host for

a lecture to a combined audience consisting of the upper forms of two or more schools in the same neighbourhood. Heads of secondary schools or colleges desiring lectures are requested to communicate with the secretary of the Fund, 7, Walbrook, E.C.4.

Dr. Boyd S. Gardner, of the Mayo Clinic, Rochester, Minnesota, will give a lecture at the Royal Dental Hospital of London, School of Dental Surgery, on Monday, November 4th, at 6 p.m., on the relationship between medicine and dentistry, emphasizing the routine use of the *x* ray from both a pre- and a post-operative standpoint; the necessity of an improved extracting technique; and the significance of laboratory investigation.

A course of post-graduate lectures on child welfare, especially intended for health visitors, nurses, midwives, and the superintendents of infant welfare centres, will be held at the Infants Hospital, Vincent Square, S.W.1, on Mondays, from 6.30 to 7.30 p.m., from October 14th to December 16th. A detailed syllabus may be obtained from the honorary secretary of the National Association for the Prevention of Infant Mortality, 117, Piccadilly, W.1. A series of elementary lectures on infant care will be given by Dr. Prudence Gaffikin in the lecture hall at Carnegie House, 117, Piccadilly, W.1, on Thursday evenings, from 7.30 to 8.30, from October 10th to December 12th. Further information may be obtained from the secretary of the National Society of Day Nurseries at the same address.

The British Institute of Philosophical Studies has arranged for a course of six lectures on the mind and nature to be delivered during the Michaelmas term by Professor Leonard J. Russell, and also for a course of the same length by Mr. E. S. Russell, D.Sc., on the interpretation of development and heredity. During the Michaelmas and Lent terms there will be a course of lectures by the director of studies, Mr. Sydney Hooper, dealing with the introduction to philosophy, and during the Lent term a course by Professor W. G. de Burgh on some aspects of the moral life. A full syllabus of these lectures can be obtained on application to the director of studies at the British Institute, 88, Kingsway, W.C.2.

Mr. F. E. Smith, D.Sc., F.R.S., director of scientific research at the Admiralty, has been appointed by His Majesty the King in Council to be secretary to the Committee of the Privy Council for Scientific and Industrial Research, with effect from October 1st, 1929, on the resignation of Mr. H. T. Tizard, F.R.S.

The London School of Hygiene and Tropical Medicine states that the transfer of Dr. J. G. Thomson to the Ross Institute, recently announced in the press, will not take place. Dr. Thomson retains his appointment in the school as director of the department of protozoology.

In many towns in England and also throughout the Empire a "health week" will be held from October 6th to 12th, under the auspices of the Health and Cleanliness Council, the offices of which are at 5, Tavistock Square, W.C.1.

At an inquest which was held on the body of a married woman, aged 29, who died on September 21st, in a hospital where she had been receiving injections of an arsenobenzol preparation, Sir Bernard Spilsbury said that death was due to syncope from the effects of chronic arsenical poisoning. The house-physician stated that 20,000 injections were given in the hospital each year, but only one death had occurred. The deceased woman had developed purpura haemorrhagica, a condition which, he said, was so rare that only twelve cases were recorded in medical literature. Three attempts had been made to save her life by blood transfusion, but without success. The coroner said he was satisfied that the injections had been given with due care, at proper intervals, and recorded a verdict of death by misadventure.

The city council of Budapest, with the object of mitigating the nuisance of excessive noise, is proposing to issue orders some of which might well be emulated in our own country. According to the *Observer* (September 15th), the continuous in whistles, tramcar bells, and motor dust carts will no longer be allowed ngines will sound their sirens only when going to a fire. Noisy motor cyclists will be severely dealt with, and those convicted a second time under the new orders will forfeit both their licences and their machines. Traffic passing schools and hospitals will be compelled to obey a "go slow" order. Workmen building or repairing houses will not be permitted to shout to each other, and carpet beating will be tolerated only if the noise cannot be heard outside the courtyard. If a single tenant in a block of flats objects to an organ-grinder the music will have to stop. No one will be allowed to turn on a loud speaker or gramophone except behind sealed windows and doors, and even in music schools windows will have to be shut during the lessons. It is expected that the new orders will come into force on January 1st.

Dr. Howard Somervell, who accompanied the last Mount Everest expedition, will broadcast from all B.B.C. stations on October 6th, at 5.15 p.m., a missionary travel talk describing the Neyyoor Hospital of the London Missionary Society, in Travancore, South India.

The seventh congress of stomatologists will be held in Paris under the presidency of Dr. Rousseau-Decelle from October 21st to the 26th, when the following subjects will be discussed: septicaemias of dental origin, introduced by MM. Thibaut and Raison; surgical treatment of periodontal infections, introduced by Dr. Lacronique; and prophylaxis of dental caries, introduced by M. Léon Frey.

The Home Service Ambulance Committee of the Joint Council of the Grand Priory in the British Realm of the Order of St. John of Jerusalem and the British Red Cross Society, reporting for the quarter ended June 30th, 1929, notes the increasing use in the country of the committee's ambulances, which are now regarded as indispensable necessities by the community at large. Motor manufacturers are paying increased attention to the design of these ambulances, the price of which ranges from £250 to £1,000. No type has yet been evolved which eliminates all road shocks to the passenger, but the use of air mattresses with adjustment of the air pressure to the weight of the patient is to be recommended. Attention is also drawn to the importance of standardization in the manufacture of both stretchers and ambulances; many of the ambulances now in use are too short for the army type of stretcher that has not got telescopic handles.

Dr. Wu Lien Teh (G. L. Tuck), Director of the Manchurian Plague Prevention Service, was delegated by the Ministry of Health at Nanking to attend the Pan-Pacific Surgical Conference at Honolulu in August. Dr. Wu contributed two papers: one on the practice of surgery and anaesthetics in ancient China, and the other on surgical aspects of the treatment of bubonic plague.

The Queen Alexandra Sanatorium Fund, which helps patients in the early stage of pulmonary tuberculosis to obtain treatment in Switzerland—weekly grants of £2 being made to selected cases—has disbursed £2,638 during the year 1928-29, as compared with £1,898 last year. The St. Moritz Aid Fund has now been amalgamated with it. The number of patients assisted during the year under review was fifty-three, as compared with forty-four in the previous year; the average stay of patients at Davos was 168 days. It is announced in the annual report that it will not be possible to make so many grants in the coming year. Inquiries should be addressed to Mr. D. Vesey, 97, Warwick Road, S.W.5.

The Food Investigation Board of the Department of Scientific and Industrial Research has issued a report embodying a critical and historical study of the pectic substances of plants by M. H. Braufoot (M. H. Carré), D.I.C., D.Sc. Pectins are gelatinous carbohydrate substances widely distributed in plant tissues, especially in fruit and vegetables and in gums and mucilages. In recent years, in view of a growing realization of the importance of pectic substances in certain industrial processes, the need has arisen for more detailed knowledge of their nature and constitution and for the development of accurate methods for their extraction and estimation. The report may be obtained from H.M. Stationery Office, price 3s. 6d. net.

According to the *Journal of the American Medical Association* of August 10th, ten of the United States prohibit the issuing of any permits to physicians for prescribing alcohol, and only a limited amount of alcohol can be prescribed in thirteen other States. The total number of permits issued to physicians throughout the country on July 1st, 1929, was 69,645, as compared with 48,097 on July 1st, 1927. The States in which most liquor licences were issued were New York, Pennsylvania, and Illinois.

W. Heinemann announces for early publication a new edition of *Acute Infectious Diseases* by Dr. J. D. Rolleston.

According to an announcement in the *Frankfurter Nachrichten* of September 19th, an American lady, Mrs. Kerckhoff of Los Angeles, has presented the sum of 4,500,000 marks (£220,000) to the corporation of Bad Nauheim for the benefit of poor persons suffering from diseases of the heart. It is proposed with part of the money to build an institute for the investigation of the pathology and therapeutics of heart disease, and the treatment of patients sent to Bad Nauheim under the social insurance scheme.

The following appointments have recently been made in foreign faculties of medicine: Professor Schede, professor of orthopaedics at Leipzig; Dr. M. Baudoin, professor of general pathology at Paris, in succession to Professor Marcel Labbé; Dr. Ricardo Cabellero, professor of the history of medicine at Rosario; and Professor Jean Lépine, dean of the medical faculty at Lyons for the next three years.

Professor Karl Friedrich Wenckebach of Vienna has been awarded the Order of Merit of the Austrian Republic.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF MENORRHAGIA.

DR. MILDRED BURGESS (London, S.W.2) writes: In reply to "Persisting," who asked on September 14th (p. 523) for suggestions for treating menorrhagia in a young unmarried woman, I have found the following useful if taken fourteen days before and during the period: Potassium iodide, 5ss–5j; syr. aurantii, 5j; aquam ad 5viii. Half an ounce is taken in water three times a day after meals.

ABDOMINAL SURGERY AT SEA.

DR. J. E. J. PALSER (London, N.10) writes: In answer to the inquiry of "T. S. S." on September 28th (p. 604), I suggest Treves and Hutchinson's *Student's Handbook of Surgical Operations* (fourth edition, 1924), published by Cassell at 10s. 6d. As a ship surgeon I took it with me. It is short, and therefore cheap, but contains all essentials, including, of course, a large proportion of abdominal surgery.

INCOME TAX.

Bad Debt Allowance.

"A. B. C." inquires whether the names and addresses of patients whose accounts have been written off as bad debts can be demanded.

*** The Inspector of taxes has no such authority, but the Commissioners, in exercising their function in hearing appeals, are entitled to put any inquiries which, in their discretion, they consider necessary, and which are relevant to the amount of the liability. The question to which "A. B. C." refers is undoubtedly relevant, and if the Commissioners have reasonable grounds for desiring some corroboration of his estimate of bad debts, they are entitled to require the information. At the same time, in the case of a medical man, the information is of so confidential a nature that the Commissioners would, in our opinion, be unlikely to insist on its production, unless they felt there were strong grounds for requiring it. We therefore suggest that "A. B. C." should, first of all, make sure that his writing-off of bad debts is not excessive, and then inform the inspector that, having regard to the confidential nature of the information, he would prefer to appeal to the Commissioners rather than to supply the required particulars.

Assistant—Board and Lodging.

"E. J. S." is working as a full-time assistant, receiving £250 per annum *plus* board and lodging, which is paid for by his principal. He is married, and supports a widowed mother and a sister under 16 years of age. He has been assessed at £351, without any special allowance.

*** If the contract is that he shall receive £250 and free board and lodging, only the £250 is assessable, although his principal can treat the whole cost to him as a professional expense. He is entitled to an allowance of £25 in respect of the assistance given to his widowed mother, provided that she has no other substantial means of support. The allowance for the sister is doubtful, as it is not clear that "E. J. S." has the legal custody of the girl. Subscriptions to medical societies are deductible provided that his principal requires him to maintain his membership of those societies. We suggest that he might request the Inspector of taxes to show how the £351 has been arrived at, pointing out at the same time that the board and lodging cost to the principal is not assessable on himself.

Motor Car Transactions.

"R. S. F." bought a Buick saloon in 1926 for £475 and sold it this year for £50, replacing it by a Riley saloon, second-hand, at a cost of £135.

*** £135 is the maximum amount allowable, as the "cost of replacement" is the basis to be applied. Our correspondent would have done better if he had claimed depreciation allowance in the past. As it is, though he cannot now make such a claim for the current financial year, he would be well advised to do so for the following years.

LETTERS, NOTES, ETC.

DATE OF FIRST RECOGNITION OF PLACENTA PRAEVIA.

DR. BETHEL SOLOMONS (Dublin) writes: In opening the discussion on placenta praevia at the Annual Meeting of the British Medical Association at Manchester with a paper published on September 21st (p. 525), I gave a short historical survey of the subject. Dr. W. J. Young of Cambridge has very kindly drawn my attention to an omission. Jacques Guillemeau in 1609 mentioned that the placenta may be the presenting part, and that the condition gives rise to dangerous haemorrhage, which Nature is unable to suppress. He treated the condition by version and extraction. I am sure the mortality was very large following on extraction.

TONSILLECTOMY AND OLD AGE.

DR. A. T. CUNNINGHAM (London, W.1) writes: In the *Journal* of September 28th (p. 604) Mr. E. G. Collins records a case under this heading. Two years ago I removed the tonsils of a lady, aged 71, who had suffered from general ill health, with minor attacks of tonsillitis for several years. Immediately before the operation she had had more severe attacks, with definitely septic tonsils. I was asked to remove her tonsils, which I did by dissection under pure chloroform anaesthesia, using the Davis-Boyle gag; she was sitting up in bed and eating solid food in forty-eight hours. At that time I looked up some literature, but I could find little reference to the operation having been performed on patients over the age of 70. I believe, however, that it is not so rare as one thinks.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LTD.

DR. HARVEY HILLIARD (London, W.2), in the course of a letter received as we go to press, writes: The annual general meeting of this society will be held on Monday afternoon next, October 7th. The agenda on the notice calling the meeting ostensibly is to inform members what business will be transacted at the meeting. In point of fact, however, three important resolutions to be moved at the meeting, due notice of which had been given, do not appear on this agenda. Thus members of the society have not been made fully aware of all the resolutions on which a vote will be taken.

THE BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

MR. VICTOR BONNEY (London, W.1) writes: In the issue of the *Times* of September 27th, in which the composition of the Council of the British College of Obstetricians and Gynaecologists was set forth, my name was included in the list of councillors. This was a mistake, and I should be obliged if you would publish this letter of correction.

A WARNING.

MEMBERS of the medical profession are advised to forward any begging letters they may receive from individuals unknown to them personally, but claiming to be widows or daughters of medical men, to the secretary of the Royal Medical Benevolent Fund, 11, Chandos Street, W.1, who is prepared to inquire into the circumstances of the case and to forward a report. We are informed that of letters which have thus been forwarded for investigation a number have proved to be from persons known to the Royal Medical Benevolent Fund as not deserving of charity.

MOTORISTS AND "WINTER TIME."

ON and after Sunday, October 6th, when summer time ceases, the hours of duty for day service A.A. road patrols will be from 9 a.m. till lighting-up time. Night service patrols will commence duty at lighting-up time and leave the road at 12 midnight. Lamps must be lit half an hour after sunset, instead of one hour as in summer time.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 53, 54, 55, 56, 57, 60, 61, and 62 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 163.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

283. Chromium Poisoning.

W. W. CARTER (*Med. Journ. and Record*, August 7th, 1929, p. 125) reports a case showing the effects on the nose and throat of chromium poisoning due to exposure to the fumes escaping during the process of plating on metallic surfaces by the electro-deposition of the metal from a solution of chromic acid varying in strength from 27 to 67 ounces in a gallon of water. The articles to be plated are immersed in this solution and subjected to the action of the electric current for six hours, oxygen being evolved from the anodes and hydrogen from the cathodes. These gases carry with them minute particles of chromic acid, which, coming in contact with the mucous membrane of the upper respiratory passages, cause symptoms of chromium poisoning, or of local poisoning when in contact with abraded skin. Although the vats may be covered and ventilated during the process, it is when they are opened for the removal of the plated articles that the fumes escape into the air and the danger of contact occurs; the risk is only slightly lessened by the use of electric fans. The symptoms are those of an ordinary coryza with an irritating cough, which is worse at night; if preventive measures and treatment are not adopted, ulceration and perforation of the cartilaginous septum ensues in two to three months. The bony septum is not affected and no incapacity results, though there may be frequent epistaxis with muco-purulent scabs and an irritating cough. The roots of the nails become affected if in contact with the solution. Prophylaxis consists in the provision of adequate exhaust ventilation of tanks and plating room, daily baths with change of clothing, the employment of an alkaline nasal spray once a day, and the use of vaseline on the hands, face, and nose, and all abraded surfaces. The author adds that affected areas should be cleansed with a strong solution of sodium bicarbonate or a dilute solution of sodium thiosulphate; this treatment is followed by the application of vaseline.

284. Influenza and Agranulocytosis.

A. BENATT and F. PFEUFFER (*Münch. med. Woch.*, August 2nd, 1929, p. 1283), who record an illustrative case, emphasize the resemblance between malignant influenza and agranulocytosis, both being characterized by their rapid course and extensive necrosis. Their patient was a lad, aged 18, who during the influenza epidemic of February–March, 1929, was suddenly taken ill with high fever, dyspnoea, and diarrhoea. Examination of the blood showed a leucopenia of 2,500, of which 12 per cent. were polymorphonuclears and the rest lymphocytes and monocytes. Death followed within twenty-four hours with signs of cardiac failure, and the necropsy showed the general lesions of influenza. The clinical course and pathological features of the case closely resembled those of agranulocytosis, except for the absence of buccal and faucial necroses.

285. Heart-block and the Stokes-Adams Syndrome.

E. DOWNIE (*Med. Journ. of Australia*, June 22nd, 1929, p. 822) has investigated a series of 27 patients with heart-block from the etiological, clinical, electro-cardiographic, and diagnostic standpoints; in all cases the block had been repeatedly demonstrated by the electro-cardiogram. Evidence of the Stokes-Adams syndrome was present in 13 of the 27 patients. Two other patients in whom this syndrome was present, though due to another cause, brought the total to 29; of these, 11 had died, while 6 could not be traced. The series collected by the author constituted 0.3 per cent. of a large number of unselected cardiac cases. The disease was found three times as often in males as in females, and most frequently in the sixth and seventh decades. Syphilis, degenerations of the [illegible]y disease were the [illegible]und that the Stokes-Adams syndrome was common when the block was variable in degree, while it occurred in only one-third of patients with constant block. In the whole series an average pulse rate of 38 was found, the average blood pressure being 160 systolic and 75 diastolic. Apart from the presence or absence of the Stokes-Adams attack and variation in the degree of block, no clinical distinction could be drawn between the group affected by, and the group free from, this syndrome. Purely syncopal attacks were found to be about twice as frequent as epileptiform seizures, and in most no warning occurred. Those patients afflicted with the Stokes-Adams syndrome lived for two to six years after the onset of symptoms, while those with constant dissociation and no attacks lived for an average of ten years. Death from progressive myocardial failure was never observed. Electro-cardiography showed that 14 of the 27 patients had complete block; extra-systoles, left-sided preponderance, right and left branch bundle block occurred as associated conditions. Concerning diagnosis, the author emphasizes the presence of a slow ventricular rate uninfluenced by exercise, atropine administration, or vagal compression, and the necessity of repeated clinical and electro-cardiographic examination of suspected patients.

286. Immunization against Scarlet Fever by a Scarlatinal Anatoxin.

G. RAMON and R. DEBRÉ (*C. R. Soc. de Biologie*, August 13th, 1929, p. 1035) have prepared a scarlatinal anatoxin from a filtrate of cultures of *Streptococcus scarlatinae* by the addition of formol. It is said to be not only perfectly harmless, but also to possess a specific antigenic action. To 171 children and 40 adults with a positive Dick reaction were given three injections of the anatoxin, the first consisting of 0.5 c.cm.; the second, three weeks later, of 1 c.cm.; and the third, a fortnight afterwards, of 1.5 to 2 c.cm. The injections were well borne, there being only a local redness with more or less swelling at the site of injection. In about half the cases a slight general reaction was observed. Three weeks after the third injection the Dick test was performed and found to be negative in 88.37 per cent. The authors remark that time will show whether the immunity thus conferred by this anatoxin is permanent.

287. Narcolepsy following Epidemic Encephalitis.

G. R. KAMMAN (*Journ. Amer. Med. Assoc.*, July 6th, 1929, p. 29), who records an illustrative case, states that narcolepsy is a rare sequel of epidemic encephalitis. The outstanding symptoms of narcolepsy, which was first described by Gelineau in 1880, are periodic attacks of involuntary sleep, and attacks of temporary loss of tone in the involuntary muscles, brought on by some emotional stimulus. Kamman's patient was a female school teacher, aged 36, in whom the two symptoms described developed after an acute attack of encephalitis, which was mistaken at the time for influenza. All forms of treatment failed, but the patient was able to continue her work as a teacher.

Surgery.

288. The Surgical Treatment of Biliary Calculosis.

A. BONADIES (*Il Policlinico*, Sez. Chir., July 15th, 1929, p. 341) publishes brief records of 123 cases of gall-stones operated upon in the last nine years. There were 9 deaths (mostly from pulmonary complications, and in severe cases with fever and jaundice) and 4 relapses. Since the use of preliminary anticatarrhal vaccination the pulmonary complications have much diminished; thus in the first 60 cases without this vaccination the pulmonary complications numbered 8, while in the second 63, with vaccination, they were only 5. To combat general infection the author recommends the free administration of glucose solution either rectally, orally, or hypodermically. Relapses may be due to overlooked small calculi, fresh formation, or possibly to pseudocolic due to spasm. The result of 90 per cent. cures and low mortality (no deaths in cases where there was no jaundice or fever) encourages the author to plead for early operation in preference to medical treatment. The subsequent history was traced in 85 out of the 123 cases.

289. Conservative Treatment of Exomphalos.

P. CAFFIER (*Zentralbl. f. Gynäk.*, August 17th, 1929, p. 2087) reports with illustrations the case of a full-time male infant born with extensive exomphalos after normal labour. The parents had had fourteen years of sterile married life before the birth of this child. The hernia was 10 cm. long, 8 cm. wide, and 7 cm. deep, and it was covered by a transparent membrane through which the stomach, intestines, and liver were plainly visible, the upper quadrant alone being covered with epithelium. The protrusion was situated mainly in the epigastrium, the urinary bladder being apparently normal. As the infant was not seen until some hours after birth an operation was contraindicated on account of the risk of sepsis, and conservative treatment in the form of 5 per cent. alcohol compresses changed frequently was employed. The

transparent hernial sac soon took on a greyish colour, and was quite opaque; by the seventh day the skin, which originally only extended over one-quarter of the hernia, had become very vascular and covered nearly half the sac, the remaining portion being overlaid by a mass of necrotic amnion. This was cast off in shreds in the course of the next few days, leaving a small granulating area, while the epithelium continued to spread over the hernia. The alcohol treatment was then discontinued and alternate dressings of silver and zinc ointment were applied, while the granulating ulcer was cauterized with silver nitrate. At the end of three months the whole hernia was covered with epithelium; its length and breadth had been diminished by 2 cm. and its depth by 3 to 4 cm. With the growth of the child and the increasing thickness of the epithelium it was possible by pressure to reduce the whole of the hernial contents between the recti into the abdominal cavity, and Caffier hopes that as the sac shrinks further and the recti increase in strength a complete cure will ultimately result. At the time of reporting the child was 4½ months old, weighed 11 lb., and, in spite of an intercurrent attack of broncho-pneumonia at 4 weeks, was developing satisfactorily. Caffier points out that in the treatment of exomphalos the question of space inside the abdominal cavity should receive careful attention. In view of the fact that this congenital condition is not the result of true extrusion of viscera, attempts at covering the protruding mass by a ventral hernia operation of the usual type, if performed before the abdominal wall and cavity have grown sufficiently to hold the additional mass, must entail the risk of either a recurrence of the hernia or bursting of the wound. He therefore recommends that the above technique, modified from a recommendation of Ahlfeld, should be adopted, at any rate as a preliminary measure, in suitable cases.

290. Facial Erysipelas.

D. SEEGAL and B. C. SEEGAL (*Journ. Amer. Med. Assoc.*, August 10th, 1929, p. 430) have made a study of 281 cases of facial erysipelas treated at the Massachusetts General Hospital from 1870 to 1927. The cases were most frequent from December to May—a period roughly coinciding with the high frequency months for haemolytic streptococcus throat carriers and wound infections; 13.5 per cent. of the cases occurred in the hospital staff, but only one was a medical officer; 48 per cent. occurred in patients after admission, about half of whom were medical cases, while the others had recently undergone some surgical operation. Of the last group slightly more than half had had their operation limited to the face. The temperature was usually high during the first two days of the disease, and about three-fourths of all the patients had a temperature of 103–104°. The natural course of facial erysipelas untreated by specific serum sometimes ended abruptly by crisis in four to seven days. The death rate was 19.6 per cent., which was reduced to 5 per cent. when patients with other serious illnesses were excluded. The highest mortality occurred among the very young and the aged.

291. Congenital Defects of the Bladder and Urethra.

G. GREY TURNER (*Brit. Journ. Surg.*, July, 1929, p. 114) describes the t[illegible] defects of the bladder and urethra by [illegible] ureters into the bowel, and gives the [illegible] most suitable age for operation is said to be between 5 and 7, though the intraperitoneal method of operation has been performed as early as the third year of life. The method of Stiles, which was that used in all but two of the 17 cases, is an intraperitoneal anastomosis of the ureters into the recto-sigmoid, carried out through an abdominal incision, about 1½ inches of the ureter being buried in the bowel wall. The ureters are anastomosed one at a time with an interval of two or three weeks. In nearly every case continence became complete, and when the renal function had become established any plastic operation necessary for the repair of deformity was performed. The congenital defects rendering the operation necessary have been exstrophy of the bladder, and epispadias with incontinence in both sexes. Among the 17 cases treated there were 4 deaths due to operation; in three of these the cause was peritonitis, and in the fourth sloughing of the ureter with pelvic peritonitis. It was observed that the deaths occurred either when both ureters had been transplanted at one operation, or after the transplantation of the second ureter in the divided operation. Sometimes several months or even two years may elapse before the system becomes quite accustomed to the altered state and the condition of the patient is stabilized, since during the intervening period complete [illegible] are [illegible] ng acquired and the kidneys Duri[illegible] to constant mild infection. [illegible] to be inadvisable to attempt any plastic procedure such as the removal of the bladder mucous membrane.

Therapeutics.

292. The Acid Treatment of Hay Fever.

H. BECKMAN (*Med. Journ. and Record*, July, 1929, p. 9) refers to Bishop's publication of 1893, setting out the uric acid theory of hay fever. Although this theory has since been discredited, Beckman believes that the empirical success of acid therapy suggests that a relative degree of alkalosis may be the underlying fault in many hay fever subjects. He points out that the pollen desensitization treatment came into prominence immediately after Bishop's publication, and that the acid therapy never obtained a fair share of publicity. In 1918 Beckman, himself a sufferer from hay fever, made a trial of treatment by nitrohydrochloric acid and obtained complete relief; he has had the opportunity of treating sixteen other patients during the last ten years, all with success. He publishes a table of results in 185 cases, including his own, and compares the results with those in 2,185 cases treated by pollen desensitization, the number of cases "completely relieved" and "greatly benefited" in the two series being approximately equal. Beckman recommends the use of a solution of nitrohydrochloric acid (U.S.P. not diluted) as follows: nitrohydrochloric acid 4 drachms, distilled water to 4 oz. One teaspoonful in two-thirds of a glass of water, followed by another glass of water, is taken after each meal, and again on retiring, as near midnight as possible. This solution gives a dose of just over ten drops of the acid to each teaspoonful; the fluid is pleasantly acid to the taste but not corrosive, though it is admitted that some physicians have stated that patients have complained that it was "too strong." Mention is made of the rarity of asthma and hay fever among diabetics, and Beckman suggests that the acidotic state may well act contrarily to the production of hay fever and other allergic diseases. In conclusion, the advantage of acid therapy over pollen desensitization is urged, by reason of its greater simplicity and the absence of unpleasant reactions. It is suggested that the study of the relation between the acid-base equilibrium and allergic diseases would repay further study.

293. Arsenobenzol Therapy of Vincent's Stomatitis.

DELGUEL and MAGIMEL (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, August 10th–20th, 1929, p. 639) remark that Vincent's gingivo-stomatitis is usually thought to be associated with oral sepsis and neglect of cleanliness; they think that this explanation is insufficient, since this form of stomatitis is very rare in comparison with the great frequency of neglected mouths. Clinical observation shows that the infection may occur in a previously perfectly healthy mouth—as, for example, when the eruption of a wisdom tooth provides an entry for saprophytic bacteria. Delayed eruption of the third molars is a frequent cause of infection. The symbiosis of the various spirochaetes found in gingivo-stomatitis, noma, and pyorrhoea has not been explained satisfactorily. The theory that all these spirochaetes have a common origin has led to the employment of arsenobenzols in the treatment of buccal spirochaetosis, but the results have been disappointing, and the local application of arsenobenzols in cases of pyorrhoea has fallen into disrepute. The authors have seen a man who was under treatment for primary syphilis; during the first course of arsenobenzol injections (which cured his chancre) he developed a severe attack of Vincent's gingivo-stomatitis, with intense systemic symptoms. The stomatitis, although unaffected by the arsenobenzol treatment, was relieved and ultimately cured by local applications of chromic acid, and of aluminium and ammonium fluorides. The authors claim that this case shows clearly the absolute uselessness of antisyphilitic treatment in Vincent's spirochaetosis.

294. Treatment of Diabetic Ketosis.

O. PUCSKO (*Med. Klinik*, August 16th, 1929, p. 1284) discusses the action of glucose and insulin upon the course of diabetic ketosis, and concludes that whether administered together or separately they are beneficial. All his cases were of the worst type, mostly juvenile diabetes. Pucsko points out that, because of this adjuvant action of glucose, the patient's comfort could be greatly increased by substituting oral glucose for many of the insulin injections. When both are combined the patient drinks 10 grams of glucose in black coffee, and, either two or four hours later, receives an injection of 20 to 40 units of insulin. Glucose alone without any other remedy will often cause disappearance of the ketone bodies, and, curiously, a reduction of glycosuria. Daily examination of the urine of one patient treated only by dieting revealed that the specific gravity was 1025, the sugar content 2.8 per cent., and that there was much acetone. On treating with only 10 grams of glucose the figures changed in one day to 1015 and 0.95; the urine volume and the amount of acetone remained about the same. Further treatment with glucose

reduced the acetone, but the glycosuria persisted at about 1 per cent. Later the treatment was combined with insulin, so that on the twenty-third day of observation, though the patient was receiving only 20 units of insulin (combined with 10 grams of glucose) daily, yet the glycosuria and ketosis had disappeared, the body weight had increased by about 17 lb., and the patient was eating bread. Several other instances are recorded in which for a time the patients were successfully treated with glucose alone. Another patient was treated with insulin alone; his progress was only fairly good until glucose was given in addition; then improvement was marked. Quite apart from the fact that this treatment can replace so many units of insulin, glucoso-insulin therapy seems to produce results that no amount of insulin alone will yield. The method is also useful when a sudden severe ketosis occurs —for instance, in coma or after an operation. Finally, patients need not be forbidden drinks sweetened with glucose once or twice daily. It should be noticed that these results apply to 10 or 20 grams of glucose; the author remarks that, perhaps, quantities greater than this may produce the opposite effect.

Anaesthetics.

295. Nitrous Oxide-Oxygen Anaesthesia in Goitre Operations.

J. L. DE COURCY (*Anesthesia and Analgesia*, July–August, 1929, p. 230) agrees with Crile that the combination of nitrous oxide with oxygen offers the safest general anaesthetic in goitre operations and is the method of choice. From the standpoint of the patient this form of anaesthesia is by far the most satisfactory yet devised. The induction of anaesthesia is rapid and free from any disagreeable features; the rapidity of recovery is equally as great, and, even after an anaesthesia lasting two or more hours, the patient may return to full consciousness in about two minutes. The dreaded after-effects of ether anaesthesia, particularly nausea and vomiting, are absent. The mixture of nitrous oxide and oxygen is, however, one of the most difficult anaesthetics to administer, and requires skill and patience. In goitre operations care must be taken that the air passages are kept clear, and the tongue must be prevented from falling backwards into the pharynx. Nitrous oxide alone produces its symptoms by oxygen deprivation, and leads to cyanosis and evidence of asphyxiation; it also raises the blood pressure. In combination with oxygen there is little danger of these untoward occurrences. Asphyxiation may also occur from compression or collapse of the trachea; this danger can be averted by the immediate administration of oxygen under pressure. During the induction of anaesthesia a high percentage of nitrous oxide must be inhaled until the patient reaches the desired stage of anaesthesia, and perhaps becomes slightly cyanotic. As the operation proceeds the percentage of oxygen is increased. Muscular twitchings can be controlled by increasing the ratio of oxygen; a loud stertor also is an indication for more oxygen. As a rule, the patient's colour and the mechanical type of respiration are the main guides as to the amount of the anaesthetic required, but the condition of the pupils and the activity of the reflexes should be examined from time to time. De Courcy states that the contraindications usually assigned for nitrous oxide do not apply when it is administered with oxygen, and that, even in aged patients, nitrous oxide-oxygen is not so dangerous as was once thought, because this combination does not cause a rise in the blood pressure.

296. Ethylene Anaesthesia.

As a result of its use in 1,000 cases of anaesthesia, covering a wide range of operations, C. E. TIPPING (*Canadian Med. Assoc. Journ.*, July, 1929, p. 62) concludes that the advantages and superiority of ethylene over any other anaesthetic far outweigh its few disadvantages. In anaesthesia with this gas the patient does not lose such a quantity of fluid from sweating as with other anaesthetics, and in the matter of causing nausea it compares favourably with nitrous oxide. The body temperature does not drop, the colour remains good, and no effect is produced on the basal metabolic rate. The kidney function may be slightly reduced, but there is no effect on the liver, and no harmful results have been noted in active lung cases. Its beneficial effects in heart lesions are probably due to the slow pulse rate. The gas is eliminated very rapidly from the lungs, and has less effect on the blood pressure than any known anaesthetic. There are no gas pains, yet peristalsis returns very rapidly. The disadvantages of ethylene are its odour and explosiveness. The former may be eliminated by starting and finishing with nitrous oxide. Tipping considers that the danger of explosion is no greater than with ether, and is unduly exaggerated. Success with this particular anaesthetic depends on proper premedication. Half an hour before operation 1/4 grain of morphine, which is better combined with 1/150 grain of atropine, should be given; in laparotomies 1/4 grain of morphine with 1/200 grain of hyoscine should be given one and a half hours before the operation. Any type of apparatus may be used. Tipping commences anaesthesia with 90 per cent. nitrous oxide and 10 per cent. oxygen. The latter is then stopped for one or two breaths, and 90 per cent. ethylene with 10 per cent. oxygen is administered. Smooth anaesthesia can be maintained with such a mixture. If, after the skin incision has been made, the blood appears dark (despite a pink colour of the skin) the percentage of oxygen is increased. When the skin is being sutured nitrous oxide is substituted for the ethylene, and when the operation is finished the bag is emptied and filled with oxygen. This eliminates any odour or headache. In only about 30 per cent. of cases is ether necessary; if so, it should be given in sufficient quantity rapidly, as this will suffice for the rest of the operation.

297. V. GHIRON (*Il Policlinico*, Sez. Chir., August 15th, 1929, p. 416) states that ethylene anaesthesia, which is employed in about 12 per cent. of the operations performed in the surgical clinic of the University of Rome, presents the following advantages over ether and chloroform. It does not do the slightest damage to the heart, lungs, liver, or kidneys; the patients recover rapidly from the anaesthetic, with a good colour and pulse; they complain only rarely of thirst and seldom suffer from vomiting. The only drawbacks to ethylene are its unpleasant smell and the rapidity with which it explodes in the neighbourhood of a light.

298. Volume Control of Spinal Anaesthesia.

R. B. STOUT (*Amer. Journ. of Surgery*, July, 1929, p. 57) describes a method of spinal anaesthetization by which the degree of anaesthesia on the body can be definitely controlled without the introduction of any substance other than novocain. The technique also prevents the wide variations in blood pressure and the nausea, vomiting, and related discomforts which frequently occur with most methods now in general use. Certain physico-chemical principles governing the diffusion of crystalloids in solution form the basis of the method. The most important factors in the volume control technique of spinal anaesthesia are: the aspiration of accurately measured volumes of spinal fluid to be used as a solvent for graded doses of novocain, and the re-injection of this spinal fluid-novocain solution at a constant measured rate without loss of fluid during the manipulation. Of equal importance is the properly timed prophylactic administration of ephedrine in amounts directly proportional to the height of anaesthesia to be produced, varied also according to the size of the patient and his vascular condition. This measure will maintain a vascular tone during anaesthesia which closely approximates the patient's normal. Tables and diagrams are given showing the different levels of anaesthesia and the dosage of novocain and ephedrine requisite to obtain these levels. The pre-operative treatment of the patient and the technique of ether anaesthetization are described. Stout also discusses the indications and contraindications for spinal anaesthesia and its benefits and complications. Failure to obtain anaesthesia may be due to two causes: one is the injection of the novocain extradurally, and the other is idiosyncrasy of the patient to novocain.

Obstetrics and Gynaecology.

299. Diabetes Insipidus and Pregnancy.

E. MOMIGLIANO (*Ann. di Ostet. e Ginecol.*, July 31st, 1929, p. 905), who records two personal cases, states that diabetes insipidus is a rare complication of pregnancy, as is shown by the fact that he has been able to collect only 31 cases from the literature between 1792 and 1927. As a general rule it appears fairly late in pregnancy. The principal symptoms, which are polyuria and polydipsia, may be occasionally accompanied by others, such as irregular temperature and anorexia. Loss of flesh is exceptional. The blood pressure is generally raised, and there is a slight diminution of the red blood cells and haemoglobin. A frequent if not constant symptom is the absence of sweating, not only under normal conditions, but also under thermal and pharmacological stimulation. In 10 of the 31 cases diabetes insipidus first appeared in the course of pregnancy, in 8 diabetes was complicated by pregnancy, in one it was congenital, while in the rest it was produced by mechanical, physical, or psychical causes, degenerative changes in the nervous system, or it was of toxi-infective origin. The prognosis depends on whether the pregnancy occurred in the course of diabetes insipidus or whether diabetes first developed in diabetes insipidus or whether diabetes first developed in pregnancy. In the former case pregnancy does not appear to exercise any special influence on the intensity of the

symptoms, while in the latter the symptoms of diabetes gradually increase until delivery and rapidly clear up in the puerperium. Treatment depends on whether the diabetes is symptomatic or idiopathic. In the symptomatic forms the treatment will obviously be guided by the cause of the condition, while in the other cases the treatment will be mainly concerned in dealing with the symptom of polyuria. Pituitary therapy may be followed by success, but the results as a whole are slight and inconstant. Drugs which have been employed are novasurol, insulin, adrenaline, urotropine, and digitalis, as well as protein therapy and lumbar puncture.

300. Ante-natal Intracranial Haemorrhages.

H. PIGEAUD (*Journ. de Méd. de Lyon*, July 5th, 1929, p. 437) does not accept the theory that meningeal haemorrhages in newborn children are, in the majority of cases, due to injury at birth. The author has examined seven embryos, expelled before the sixth month of pregnancy; in six of these the membranes were intact. Obviously these embryos were protected from pressure by their small size and the presence of liquor amnii. All showed extensive subdural and subarachnoid haemorrhages, while examination of other organs revealed many visceral haemorrhages (especially in the liver and spleen), and also inflammatory changes in the choroidal plexuses and in the hepatic parenchyma. In one case the foetus was mummified. The seventh specimen, a foetus in the fourth month, showed definite symptoms of hereditary syphilis. The subdural and visceral haemorrhages were usually surrounded by an intensely vascular zone with numerous macrophages containing blood pigment. These changes indicated that the haemorrhages had occurred at a period considerably antecedent to the date of foetal death, and therefore were not connected with any mechanical injury. Pigeaud concludes that the majority of these embryos were syphilitic, and that congenital syphilis is the principal, if not the sole, cause of ante-natal intracranial haemorrhage.

301. Treatment of Puerperal Infections.

A. FALCONE (*Riv. d'Ostet. e Ginecol. Prat.*, May, 1929, p. 15) has found that puerperal infections yield satisfactorily to treatment with injections of protein, and also of a ferment-producing substance—stomosine. He records 8 cases treated with protein and 11 cases with stomosine, without any failures. The protein used was sterile milk, of which 5 c.cm. were given as soon as a rise of temperature was noted. One patient required only one injection before the temperature fell; another had three injections, and the remainder two injections each. There were no anaphylactic symptoms, and the patients exhibited great tolerance to the treatment. The author considers the lactalbumin to be the therapeutic agent, but quotes Linding as stating that the casein promotes the disintegration of the antibodies. The curative action of stomosine is attributed to the liberation of ferments. One or two intramuscular injections were given, sometimes preceded by an injection of adrenaline; in some cases the reaction was considerable, with a brief rise of temperature, in others there was no reaction. There was an immediate fall of temperature in some patients, in others lysis ensued.

Pathology.

302. Serological Control of Kala-azar Treatment.
